CLIENT-SERVER INDEPENDENT INTERMEDIARY MECHANISM

FIELD OF THE INVENTION

The present invention relates to client-server communication, and more specifically, to using an independent intermediary mechanism between a client and a server.

BACKGROUND

The World-Wide Web (WWW, W3, the Web) is an Internet client-server hypertext distributed information retrieval system. An extensive user community has developed on the Web since its introduction.

Figure 1 is a block diagram of a prior art client-server system. The client A 110 can access destination servers DS1-DS3 150-170. Similarly, other clients B and C, 120 130, can access the destination servers DS1-3 150-170. Each destination server may provide different services, information, or other data to the user.

On the Web everything (documents, menus, indices) is represented to the user as hypertext objects in hypertext markup language (HTML) format, or as Java, or JavaScript objects, or other data types. Hypertext links refer to other documents by their uniform resource identifiers (URIs). The client program, known as a browser, e.g. NCSA Mosaic, Netscape Navigator, runs on the user's computer and provides two basic navigation operations: to follow a link or to send a query to a server. Users access the web through these browsers.

Users often access the web from multiple locations. Users may access the web from their office, at different locations at work, at home, or on the road. Libraries and Internet cafes make web access available on a walk-in basis as well.

A user accesses a server by typing the URI of the server into the browser's address window. The browser then connects to the server corresponding to this URI. Another method of accessing a web site is by selecting the web site from the list of bookmarks. The list of bookmarks is resident in the browser in the user's computer. Thus, if a user wishes to have similar bookmarks on multiple computers, he or she must

manually copy the bookmarks and transfer them between the computers. This process is inconvenient.

Furthermore, many servers use cookies to store information about the user. This information may include the user name, password, previous interests, etc. These cookies are also stored in the user's browser. Again, this means that if the user is accessing the Internet from multiple computers, the user's cookies have to be duplicated into multiple computers. This process is inconvenient.

Many users have multiple accounts on different computer systems. For example, a user may have an account with a bank, an e-mail account, a personalized portal site account, and an account on an e-commerce server. Currently, the users must log into each of these accounts by remembering and providing his or her user name and password. For security, each of these user names and passwords should be different. Remembering different names and passwords is inconvenient to the user. Thus, a method for a simple log-in into various accounts from any computer would be advantageous.

Most clients and servers support "forms" which allow the user to enter arbitrary text as well as selecting options from customizable menus and on/off switches. As more business is transacted on the Web, forms are proliferating. The forms may include forms for requesting further information, for ordering items from the Web, for registering for a Web site, etc. However, the user generally can not get a copy of the information filled into the form. The user can either print the page when the form is filled in, generating a paper copy, or rely on the server to respond in a manner that permits the user to make a record of the information entered in to the form. A method of tracking information filled into forms would be advantageous. Furthermore, vendors may respond with an order number or other useful information. The user can keep a copy of this page, which is generally only temporarily available, by printing it, or copying down the information provided. A method of attaching this vendor response to the original order information and making both available to the user would be advantageous.

Furthermore, currently, the user has to fill out each of these forms separately. Generally, the forms request the same types of information, i.e. name, address,

telephone number, e-mail address, etc. The user has to enter all of this information for each form. This is repetitious and takes time. Additionally, if such information as credit card number or social security number is requested, the user has to pull out the credit card and copy a long string of numbers. This makes errors likely. Furthermore, the user has to verify that a Web site that requests a credit card number or similar confidential information is of the appropriate level of security for the user to feel comfortable sending the information over the Web. An improved method of filling out forms would be advantageous.

SUMMARY OF THE INVENTION

A method and apparatus of a client-server independent intermediary mechanism (IIM) is described. The method comprises displaying a frame including a user interface of the IIM (IIM frame), and a second frame framing a destination server display area (DSDA). The method further comprises retrieving data for display from a destination server, and instrumenting the data prior to display such that future data retrieved from a destination server is displayed in the DSDA, without writing over the IIM frame.

BRIEF DESCRIPTION OF THE DRAWINGS

The present invention is illustrated by way of example, and not by way of limitation, in the figures of the accompanying drawings and in which like reference numerals refer to similar elements and in which:

Figure 1 is a block diagram of a prior art client-server system.

Figure 2 is a block diagram of one embodiment of the client-server system including the independent intermediary mechanism.

Figure 3A is a block diagram of one embodiment of the client-server system including multiple independent intermediary mechanisms.

Figure 3B is a block diagram of another embodiment of the client-server system including multiple independent intermediary mechanisms.

Figure 4 is a block diagram of one embodiment of the independent intermediary mechanism.

Figure 5 is a block diagram of one embodiment of the layout of the user interface of the independent intermediary mechanism.

Figure 6 is a flowchart of an overview of using the independent intermediary mechanism.

Figure 7 is a flowchart of one embodiment of the process of displaying information from a destination server through the independent intermediary mechanism.

Figure 8 illustrates one embodiment of the user interface of the independent intermediary mechanism.

Figure 9 illustrates another embodiment of the user interface of the independent intermediary mechanism.

Figure 10 is a flowchart of one embodiment of the form fill functionality.

Figure 11 is a flowchart of one embodiment of the learning process in the database.

Figure 12A is a flowchart of one embodiment of adding accounts.

Figure 12B is a flowchart of one embodiment of accessing an account through an auto-log-in feature.

Figure 13 is a flowchart of one embodiment of the transaction management functionality.

Figure 14 illustrates one embodiment of the listing of transactions.

Figure 15A is a flowchart of one embodiment of selection of a home page or a bookmark.

Figure 15B is a flowchart of one embodiment of using the bookmark functionality.

Figure 15C is a flowchart of one embodiment of using the history functionality.

Figure 16A-C are tables illustrating examples of redirecting references to DS through IIM.

Figure 17 is a table illustrating examples of making the IIM user interface frame persistent.

Figure 18 is a table illustrating examples of accessing cookies from the IIM.

Figure 19 is a table illustrating examples of preserving top frame or IIM frame integrity for DS.

DETAILED DESCRIPTION

A client-server independent intermediary mechanism is described. The independent intermediary mechanism (IIM) mediates information exchanged between a client and servers by having the client-server communication pass through the IIM. This allows the IIM to offer various services. For one embodiment, the IIM may be used to have a central web-accessible set of bookmarks. The IIM may further provide tracking of transactions on the web, providing a user-accessible transaction record. The IIM may further be used to fill in various forms automatically. The IIM may further be used to access multiple accounts, such as e-mail accounts, bank accounts, etc. with a single button. The IIM may further be used to store the user's profile, including passwords to various pages, etc. These and other uses of the IIM are described below.

Figure 2 is a block diagram of one embodiment of the client-server system including the independent intermediary mechanism. Multiple clients A-C 210, 215, 220 access multiple destination servers (DSs) 280, 285, 290, through the independent intermediary mechanism (IIM) 250. Client A 210 is described as an example. It is to be understood that multiple clients are implemented in similar ways.

Client A 210 accesses the IIM 250. For one embodiment, this occurs when the user of the client A 210 accesses the web site hosting the IIM 250. When the IIM 250 is accessed, a new client component (CC) 230 is established. The client component(s) 230, 235, 240 and the server component 260 together form the IIM 250. For one embodiment, the IIM 250 is located on a server accessed by the client A 210 through an Internet connection. For another embodiment, the IIM 250 is located within the local Intranet of client A 210. For yet another embodiment, the IIM 250 is located on the client's own computer.

For one embodiment, the client component 230 is established on the local computer of the client 210. For another embodiment, the client component 230 is on a server, or on a third computer system. The client component 230 is created in response to the client 210 connecting to the IIM 250.

The client A 210 has a connection to the server component 260 through the client component 230. For one embodiment, the client A 210 also establishes a direct connection with the server component 260. This direct connection may be used to

communicate certain information directly between the server component 260 and the client A 210. The client 210 accesses the destination servers DS1-3 280, 285, 290 through the IIM 250. For one embodiment, all of the communication between the destination server DS1 280 and the client A 210 is routed through the IIM 250. For another embodiment, certain communications are routed directly between the client A 210 and the destination server 280. For example, certain large images that do not invoke other images or other data may be routed directly in order to speed up processing.

The number of client components 230, 235, 240 depends on the number of clients 210, 215, 220 coupled to the server component 260 at any one time. For one embodiment, the server component 260 consists of multiple components that act together. A block diagram of one embodiment of the IIM 250 may be found in Figure 4, below.

Figure 3A is a block diagram of one embodiment of the client-server system including multiple independent intermediary mechanisms 350, 360. Each IIM 350, 360 is shown having a corresponding server component, 355, 365. For another embodiment, the server components 355, 365 may be located on a single server, or within a single IIM. Having server components 355, 365 coupled together may serve multiple purposes. For example, if a single IIM 350 has too many users connected to it, the IIM 350 may redirect users to a second IIM 360. For another embodiment, a user may log on to a local IIM 350, for speed reasons, and the local IIM 350 may connect to the user's "home" IIM 360 to retrieve the user's data. For yet another embodiment, the user can connect to their "home" IIM 350, which is remote, and the "home" IIM 350 may redirect the user to a local IIM 360 and send the user's data to the local IIM 360. In this way, the user's connection to the IIM 350, 360 may be optimized.

Figure 3B is a block diagram of another embodiment of the client-server system including multiple independent intermediary mechanisms. In this example, a client 310 is coupled to two IIMs 350, 360. Generally, the client 310 first connects to the first IIM 350. Then, through the user interface of the first IIM, the client 310 connects to the second IIM 360. This may be advantageous if, for example, the first IIM 350 and second IIM 360 provide different services. Thus, for example, one IIM 360 may provide additional account management features, while the other IIM 350 provides form-fill

features. By connecting to both IIMs 350, 360, in series, the user has access to the features provided by both IIMs 350, 360.

Figure 4 is a block diagram of one embodiment of the independent intermediary mechanism. The IIM 400 has three layers. The lowest layer of the IIM 400 is the core engine 410. The core engine 410 includes a server component SC and a client component CC. The Server Component, for one embodiment, is resident on the server, and handles all remote actions. The Client Component, for one embodiment, is resident on the client's system, while the client is connected to the IIM 400. For one embodiment, the client component is automatically removed from the client's system when the client disconnects from the IIM 400. The lowest layer also includes a Cookie Manager 413, for managing any cookies received from and being sent to the destination server. The use of such cookies is discussed in more detail below. Furthermore, the lowest layer may include a Activation Manager 416. The Activation Manager 416 determines if information is being transmitted by the destination server. For one embodiment, the Activation Manager 416 further determines if information is being initiated by a user's action. Information transmitted between the DS and the client is instrumented by the IIM 400, as will be described below. The Activation Manager 416 detects when the IIM 400 should review communication between the client and the DS.

The second layer is the application/UI framework layer 420. The application/UI framework layer 420 establishes the basic user interface and IIM engine. The application/UI framework layer 420 creates a persistent frame for the IIM 400. For one embodiment, the application/UI framework layer 420 further includes an instrumenting manager 425, for instrumenting data flowing from the destination server to the client, through the IIM 400. This process of instrumenting is described in more detail below.

The third layer is the applications layer. The applications layer includes multiple applications. The applications listed here are listed as an example, and are not a complete list. The applications layer, for example, may include a Navigation Manager 430. The Navigation Manager 430 permits a user to navigate from destination server to destination server using the IIM 400. The applications layer may further include a Transaction Manager 440.

The Transaction Manager 440 tracks the user's transactions, stores them, and makes them available for the user's review. Transactions are interactions in which a user submits information to a destination server, for example to order an item, ask a question, or otherwise interact with the destination server. The Transaction Manager 440 tracks the data submitted by the user, and any response from the destination server, and permits the user to access this information.

The Account Manager 450 permits the user to log into a variety of accounts, from e-mail to stock trading accounts, using a single click. The Account Manager 450 further permits the user to add accounts to this list. The Form Manager 460 permits the user to fill out forms encountered on destination servers via a single click. This is extremely useful for users that transact business on the web, and often fill out identical forms many times. The Profile Manager 470 is the database of the user's personal information. This information may be edited by the user, and is used to fill in forms via the form manager 460. The Database Manager 480 manages the various databases of the IIM 400.

The Bookmark Manager 490 permits the user to manage bookmarks maintained within the IIM 400. Having bookmarks, URIs of pages the user wishes to save, available in the IIM 400 permits the user to access his or her bookmark list from any computer.

The History Manager 495 permits the user to manipulate the history list of sites the user has previously visited. For one embodiment, the user can change the permanence of the history lists, for another embodiment, the user can delete certain sites from the history list.

The Homepage Manager 497 permits the user to set a homepage that is displayed when the user initially connects to the server providing the IIM 400.

As can be seen, the IIM provides multiple functionalities. A single IIM 400 may include all of the functionalities described above, additional functionalities, or some subset of these functionalities. The IIM's functionality may be extended with additional features.

Figure 5 is a block diagram of one embodiment of the layout of the user interface of the independent intermediary mechanism. The client browser application window 510 is displayed by a browser, such as Netscape Navigator or Microsoft Internet Explorer. The client side display area (CSDA) 520 is the display area available in the

browser application window 510. Most browsers have a toolbar and other displays within the browser application window 510. For one embodiment, the IIM is designed to minimize the area of the browser application window that is not the CSDA 520.

The CSDA 520 includes a toolbar frame 530. Although the tool bar frame 530 is referred to as a frame, for one embodiment, the tool bar frame 530 may be implemented in a non-frame format. For one embodiment, the tool bar may be implemented as a separate window. For another embodiment, the tool bar may be implemented as part of the display, not as a frame.

The CSDA 520 further includes a destination server display area (DSDA) 540. The DSDA 540 is the area in which all information from destination servers is presented.

The CSDA 520 further includes a communications frame 550. The communications frame 550 is for communication between the client side and server side of the IIM. Generally, the communications frame 550 is hidden from the user's view. Thus, the user would not see the communication between the client component and the server component.

Figure 6 is a flowchart of an overview of using the independent intermediary mechanism. At block 610, the user connects to the IIM through the client browser. For one embodiment, this is done by typing the address of the IIM into the address window of the browser. For one embodiment, the IIM may be the preset homepage of the user, or a bookmark in the client browser.

At block 615, the user connects to a destination server (DS) through the IIM. For one embodiment, this is done by typing the address of the destination server into the address window of the IIM. For another embodiment, the user may select an address from a history list of previously visited sites, from a bookmark list in the IIM, or the destination server may be a preset homepage in the IIM. The IIM records the DS in the history database. The history database tracks the web sites that the user has visited in the past. Such a history database may be useful to permit backtracking, or to visit previously visited sites. For one embodiment, this history database is maintained for a fixed duration of time, or a user preset period of time. For another embodiment, the history database is maintained indefinitely.

At block 620, the process changes the reference to DS to go through the IIM and load the information from the DS in the DSDA, maintaining the IIM frame. This is described in more detail below.

At block 625, the IIM determines whether the user submitted information to the destination server. For one embodiment, the actual test is whether information that is "sensitive" or "of interest" is submitted to the DS. For example, if a user selected a radio button for the next display, the response would be "no" even though some information was submitted. For one embodiment, the answer to this query is yes only if information that is in the user's profile is submitted. For one embodiment, the answer to this query is provided by the user through the user interface. If the answer is yes, the process continues to block 630.

At block 630, the user's communication with the DS is recorded in the user's transaction database. For example, if the user ordered an item from a destination server site, the form that was filled in by the user, including all of the information filled in, would be recorded in the transaction database. This transaction database is available to the user. The process then continues to block 635. If, at block 625, the answer was no, the process continues directly to block 635.

At block 635, the IIM forwards the communication, i.e. the information submitted by the user, to the DS. This communication includes relevant cookies. A cookie is a packet of information sent by a destination server to a browser and then sent back by the browser each time it accesses that server. Cookies can contain any arbitrary information the server chooses and they are used to maintain state between otherwise stateless transactions. Generally, cookies are maintained in a user's browser. However, for one embodiment, the IIM maintains the user's cookies. This permits a user to log into a site, and have the appropriate cookies available, no matter from what web client device or client browser the user accesses the site.

At block 640, the process determines whether the destination server responded to the user's submission of information. For one embodiment, some destination servers respond, with a thank you page, other data pertaining to order number, shipping code, delivery date, etc., when information is submitted to them. If the destination server responds at block 640, the process continues to block 645.

At block 645, the DS's response is recorded in the user's transaction database, and associated with the user's submitted information. Thus, when the user reviews the transaction, he or she can review the entire transaction, including the DS's response.

At block 650, the IIM instruments the DS's response, stores any cookies returned by the DS, and forwards the response to the client browser. One embodiment of this process is illustrated in more detail in Figure 7, below. Tables of some results of the process of instrumenting are illustrated in Figures 16A-C, and Figures 17-19.

At block 655, the process tests whether the user continues to browse through the IIM. The user continues to browse, the process returns to block 615. Otherwise, the process ends at block 660.

Figure 7 is a flowchart of one embodiment of the process of instrumenting data displayed from a destination server through the independent intermediary mechanism. For one embodiment, Figure 7 is a more detailed flowchart of block 650, in Figure 6. At block 705, the IIM receives a communication from the DS. For one embodiment, this occurs in response to a user contacting a DS through the IIM.

At block 710, the process tests whether there is a cookie or multiple cookies associated with the communication. Cookies may be sent by the DS to the client, to be stored on the client browser. If a cookie is associated with the communication, the process continues to block 715. At block 715, the IIM cookie database is updated with the new cookie. For one embodiment, cookies sent by the DS to the client browser are handled through the IIM. Thus, the IIM would store all of the cookies for a DS, and give the DS its cookies. This is advantageous because it permits a user to access a DS from any computer, and all of the user's cookies are immediately available through the IIM. The process then continues to block 725. If no cookies were associated with the communication, the process continues directly to block 725.

At block 725, the process parses the code to find the next keyword. For one embodiment, keywords are tags in HTML, or known keywords in Java or JavaScript. Figures 16-19 illustrate some examples of keywords that may trigger this process. For another embodiment, keywords may be any triggering signal that indicates that an action may be performed.

At block 730, the process tests whether a keyword was found. If no keyword was found, the process continues to block 735, and ends. If the communication has no remaining keywords, the document has been fully instrumented, and is ready for display to the user. For one embodiment, certain communications may have no keywords at all. In that case, this process would end after a single pass. For yet another embodiment, under some circumstances, the process may ignore certain keywords. Certain references are not altered in the communication. For example, references that call static images, images that do not communicate information to the user and do not have embedded references, may be of no interest. For example, if the keyword calls a large passive figure with multiple components, the process may ignore the entire figure, by tagging figure related communications, and exit out of this process even if keywords remain. By altering only those references that are of interest, the process may be sped up. If a keyword was found, the process continues to block 740.

At block 740, the process tests whether the keyword is an attempt to access a cookie from the cookie database. If the keyword is an attempt to access a cookie, the process continues to block 745. At block 745, the access attempt is changed to fetch the cookie from the IIM's cookie database. Some examples of this process are provided in Figure 18. For one embodiment, the IIM's cookie database may access the client browser's cookie database in order to determine whether there are additional cookies on the client browser. For one embodiment, the IIM can, with the user's permission, copy cookies from the browser cookie database to the IIM. This simplifies moving from direct access of a DS to accessing a DS through the IIM. The process then continues to block 750.

If the keyword is not an attempt to access a cookie, the process continues directly to block 750.

At block 750, the process tests whether the keyword is an attempt to access the top frame or IIM frame. If the keyword is an attempt to access the top frame or IIM frame, the process continues to block 755. At block 755, the access attempt is changed to access the top area of the destination server display area (DSDA). Some examples of this process are provided in Figure 17. The process then continues to block 760.

If the keyword is not an attempt to access the top of IIM frame, the process continues directly to block 760.

At block 760, the process tests whether the keyword is a reference to the destination server. If the keyword is a reference to the destination server, the process continues to block 765. At block 765, the reference is changed to be fetched through the IIM. Some examples of this process are provided in Figure 16A-C. The process then continues to block 770.

If the keyword is not a reference to the destination server, the process continues directly to block 770.

At block 770, the process tests whether the keyword is an attempt to access data from the top frame or IIM frame. If the keyword is an attempt to access data from the top frame or IIM frame, the process continues to block 775. At block 775, the access attempt is changed to fetch data from the topmost frame of the DSDA. Some examples of this process are provided in Figure 19. The process then returns to block 725, and parses to find the next keyword.

For one embodiment, the above process may be triggered by a user. For example, a user may select a link, activate a JavaScript function, or otherwise initiate communication between the destination server and the client. The same process may occur in response to a cookie being sent or received, or a keyword being found as described above with respect to Figure 7.

Figure 8 illustrates one embodiment of the user interface of the independent intermediary mechanism. The user interface includes a browser toolbar 805. For one embodiment, the IIM may configure the browser such that the browser toolbar area 805 is not displayed when the IIM is active. The display area 810 of the browser includes the IIM toolbar 820, a hidden communications frame 815, and the destination server display area 845.

The IIM toolbar 820 includes the known browser controls 825, such as back, forward, refresh, stop, etc. Additional browser controls 825 may be added. The toolbar 820 further includes an address entry control 830, where a user can type a destination server address in order to access the DS.

The IIM toolbar 820 may further include buttons, or other selection mechanisms that permit a user to configure and use the IIM. The buttons may include Home, selecting a user's preset homepage, etc. The homepage is preset using the Set Home button 852. The buttons may further include the Mall button, giving one-button access to shopping. The buttons may further include Tags 860, displaying a list of a user's bookmarks. Bookmarks are added by selecting the Tag Address while visiting a web site, or by selecting the Tag Address button 862, and typing the address of a location to be bookmarked.

The buttons may further include Accounts 865, permitting single-button log-on to a variety of accounts. These accounts are added with the Add Account button 867, as will be described below.

The buttons may also include a Transactions button 870, that permits a user to review his or her transactions. This is illustrated in the destination server display area 845 of Figure 8. The Profile button 875 permits the user to enter his or her personal data. The Fill-Form button 880 permits the user to fill in a form using the personal data from the user's profile or by using information submitted previously using the same form. If a form is displayed on the destination server display area 845, and the user selects the fill-form button 880, the form is automatically filled in with the user's information. The Clear Form button 882 permits a user to remove the information filled into a form. This provides an additional level of security to the user.

The Admin button 885 provides access to account administration services. For one embodiment, the Admin button 885 is only available to those users who are authorized administrators. For one embodiment, the Admin button 885 is only displayed if the user is authorized to access account administration services.

The toolbar 820 further includes a Bye button 890, which logs off the user from the IIM. The toolbar 820 illustrated is exemplary. The content and organization of the buttons on the toolbar 820 may be changed without changing the invention.

Figure 9 illustrates another embodiment of the user interface of the independent intermediary mechanism. As can be seen, the user interface may be flexibly implemented. Certain features may be provided by one interface and not provided by another. Furthermore, the look and feel of the user interface may be altered. The user

may, for example, access all of the IIM features through pull-down menus, such as the pull-down menu 935, or radio buttons instead of buttons. One skilled in the art understands other types of user interface changes that may be made without departing from the broader spirit and scope of the invention as set forth in the appended claims.

Figure 10 is a flowchart of one embodiment of the form fill functionality. At block 1010, a document with a form is displayed. For one embodiment, this is a result of a user accessing a destination server location that includes a form. This form may be an order form, an information request form, or any other form that may be encountered on the Web.

At block 1015, the user requests the form-fill function through the IIM user interface. For one embodiment, the user presses the form-fill button. For another embodiment, the form fill may be automated. For yet another embodiment, the user can select whether the form fill function is automatically engaged.

At block 1020, the process determines whether the form is in the user's transaction database. The user's transaction database has records of previously accessed and filled-in forms for the particular user. The transaction database may maintain such records for a limited time, or the user may delete transaction records. Thus, merely because a user has been to a particular site previously may not mean that the form is in the user's transaction database. If the form is in the user's transaction database, the process continues to block 1040, otherwise, the process continues to block 1025.

At block 1025, the process determines whether the form is in the form database. The form database is maintained by the IIM and includes "known" forms. Such known forms have associations between form control identifiers in the form and profile items. Thus, for example, a form control identifier that is labeled "name" may have a link to the "First Name Last Name" item in the user profile. If the form is known, the process continues to block 1030. At block 1030, the form control identifiers in the form are filled in from the user profile. The process then returns to block 1055.

If the form is not known, the process continues to block 1035. At block 1035, the form controls are identified, based on the name of each control. Each control name is associated with entries in the user profile. The process then continues to block 1030,

and the data is filled into the form from the user profile. For one embodiment, block 1035 is skipped. This type of "guessing" may be user enabled, or may be only attempted for forms that are similar to known forms.

At block 1020, if the form was found in the user's transaction database, the process continued to block 1040. At block 1040, the process tests whether any data in the user profile has been changed since the transaction in the transaction database was recorded. Transaction records are dated, as are changes to the user profile. A user profile may be changed by the user, for example, to change a credit card expiration date, number, or home address. If a user profile change of a relevant field is dated after the transaction record date, the process continues to block 1045, otherwise, the process continues directly to block 1050.

At block 1045, the changed information is filled in from the user profile. In this way, the user only had to update his or her records once, in the profile, and that change is carried through the IIM. For one embodiment, this step may be skipped. For another embodiment, this step may be user enabled.

At block 1050, the remaining form control identifiers in the form are filled with data from the transaction database. The process then continues to block 1055.

At block 1055, the filled-in form is displayed to the user, and the user is permitted to edit the data in the form. The user, for example, may not wish to provide certain data to a destination server. The user may chose to erase such data. Alternatively, the form may request data that is not found in the user's profile. The user may chose to fill in such data.

At block 1060, the user submits the form to the destination server. For one embodiment, the IIM stores the information submitted to the server in the user's transaction database. This is illustrated in Figure 13 below. At block 1065, the process ends. For one embodiment, the user may optionally select whether to use the user profile, transaction database, or both, and in what order, for form fill functions.

Figure 11 is a flowchart of one embodiment of the learning process in the database. At block 1110, a privileged user connects to the IIM. For one embodiment, this privileged user is an employee of the group maintaining the IIM. For another

embodiment, this "user" is an artificial intelligence unit that is used to identify forms, as will be described below. Such intelligent recognition programs are known in the art.

At block 1120, the privileged user accesses a destination server page with a form through the IIM. At block 1130, the IIM displays a user interface for cataloguing the form.

At block 1140, the user maps each form control to an element in the user profile object. The user profile is set up to contain a large number of possible data elements. Each form control should have a corresponding profile element. If no profile element is found for a form control, that form control may be tagged as "form specific." For one embodiment, multiple elements in the user profile may be associated with a single form control, or vice versa.

At block 1150, other information about the form is added. This information may include such information as the address of the form, whether the connection with the destination server that serves the form is a secure connection, whether the form is of a particular classification, etc.

At block 1160, the user submits the information to the IIM.

At block 1170, the IIM updates the form identification and form description in the form database to include the information added by the user. For one embodiment, the updating is a periodic batch updating. For one embodiment, a single central form database is maintained. In that instance, the IIM's updating may include sending the new form to other IIMs. Alternatively, each IIM may maintain its own separate form database. For yet another embodiment, an IIM may have a central form database, and a separate internal form database. This may be useful, for example, for an IIM implemented within a company which has the general form database for pages accessed outside the company, and a separate internal database for internal web page forms.

At block 1180, the process ends. Of course, the privileged user may enter multiple entries, and may start the process again at block 1120.

Figure 12A is a flowchart of one embodiment of adding accounts. At block 1210, the user connects to the IIM through a client browser. At block 1220, the user accesses a destination server through the IIM. For one embodiment, the user accesses the account

log-in page of the DS. This may be, for example, the account log-in page of the user's bank, of a portal, or of any other DS.

At block 1230, the user requests to add the account to the user's account database. Each user may have an account database, which includes a list of accounts the user can access with a single click.

At block 1235, the process determines whether the user has submitted log-in information to the account log-in page. If the user has not submitted the information, the process continues to block 1240, and the user is prompted to complete the log-in process. For one embodiment, if the account log-in process includes multiple pages, the user may indicate the end of the log-in process by pressing a certain key, or through other means. The process then continues to block 1245. If the user has submitted all of the log-in information, the process continues to block 1245 directly.

At block 1245, the account entry is added to the user's account database. The account log-in information and data of account entry creation are recorded. For one embodiment, further information may be recorded. For yet another embodiment, only the user's log-in procedure is recorded.

At block 1250, the account information is submitted to the DS for login. At block 1255, the process ends.

Figure 12B is a flowchart of one embodiment of accessing an account through an auto-log-in feature. At block 1260, the user connects to the IIM. At block 1265, the user accesses the account auto-log-in feature using the IIM user interface. For one embodiment, this is done by the user pushing the account button.

At block 1270, the user selects an account to log into. For one embodiment, the user may have multiple accounts. In that instance, the IIM displays the accounts that the user has. For another embodiment, if the user only has a single account, that account is automatically selected when the user accesses the auto-log-in feature.

At block 1275, the IIM retrieves login information from the user's account database. As discussed above, the user's previous account log-in is monitored and recorded. This information is retrieved at block 1275.

At block 1280, the IIM sends the log-in information to the appropriate destination server to log-in the user. The account information includes the address of the DS. The IIM accesses the DS as a client, and sends the user's information.

At block 1285, the IIM instruments the DS's response and sends it to the user's browser for display. As discussed above, the response is instrumented such that references of interest are routed through the IIM. The user can now use the account, as usual. At block 1290, the process ends.

Figure 13 is a flowchart of one embodiment of the transaction management functionality. At block 1310, the user connects to the IIM.

At block 1320, the user transmits information in a form to the destination server. For one embodiment, the user first accesses a destination server page including a form through the IIM. This form may be an order form, an e-mail form, or any other type of form. The user then fills in the form and submits it to the DS. For one embodiment, the user may use the form-fill method described above to fill-in the form.

At block 1330, the process determines whether the user sent the user's e-mail address to the DS. The user may submit his or her e-mail address so the DS can send responses directly to the user's e-mail. For example, certain systems may send confirmation e-mails or alert notices to the user via e-mail. If the user submitted his or her e-mail address, the process continues to block 1340. Otherwise, the process continues directly to block 1350.

At block 1340, the e-mail address submitted to the DS is altered. Specifically, the e-mail address is bifurcated, generated two e-mails. The first e-mail goes to the user's e-mail address, as entered. The second e-mail goes to the IIM. The second e-mail includes in its address the IIM and the transaction tag that identifies the transaction number to which the e-mail belongs. This allows the IIM to handle the e-mail. The process then returns to block 1350.

At block 1350, the IIM records a transaction in the user's transaction database and associates the submitted information with the transaction. The transaction, for one embodiment, has a transaction number.

At block 1360, the IIM determines whether there is a response from the DS. If there is a response, the process continues to block 1370. Otherwise, the process continues directly to block 1380.

At block 1370, the IIM records the response from the DS in the user's transaction database. For one embodiment, the destination server may respond to the user. This response is associated with the transaction record. In this way, the user may review the transaction record, including the response.

At block 1380, further information is recorded about the transaction. For one embodiment, this information may include the date and time of the transaction, and other information.

At block 1390, any notes, data, or e-mails received with the transaction tag are attached to the transaction. This may occur at any time, while the transaction is being recorded, or after that. The user may attach any data to the transaction, and the IIM may automatically attach any e-mails received with the transaction tag.

At block 1395, the process ends.

Figure 14 illustrates one embodiment of the listing of transactions. The transaction list 1410 may be sorted by date, using a menu 1425. The transactions may also be sorted by type 1435. For one embodiment, alternative methods of searching transactions may also be implemented. For example, a user may search the transaction records for purchases from a certain destination server.

Each transaction record may include one or more of the following: date 1420, transaction type 1430, and description 1440 of the transaction. The record may further include the place 1450, the location from where the transaction was recorded. The user may add and edit additional notes 1460. Furthermore, the user may also add attachments 1415 to the transaction record. For example, the user may attach e-mails, documents, video, or other types of data. For one embodiment, e-mails may be redirected through the IIM and automatically attached to the transaction.

The vendor response 1470 is also recorded. The information the user provided 1480 during the transaction is also included in the transaction record. The transaction may further include the information whether the transaction belongs to one of the

accounts 1490 in the user's account database. The user is permitted to delete selected transaction records using a delete button 1465.

Figure 15A is a flowchart of one embodiment of selection of a home page. The user connects to the IIM at block 1505.

At block 1510, the user accesses a destination server page through the IIM. At block 1515, the process determines which option the user is selecting.

If the user is selecting the add bookmark option, the process continues to block 1525. At block 1525, the address of the page is added to the user's bookmark database. This database is accessible to the user, to permit the user to access various web sites without typing the address of the site. The process then continues to block 1530, and ends.

If the user selected the set home page option at block 1515, the address of the page is set as the user's homepage. The user's homepage is called up when the user initially connects to the IIM. For one embodiment, the homepage is preset. For another embodiment, the user may not alter the homepage, and the homepage is customizable but includes advertising. The process then continues to block 1530, and ends.

Figure 15B is a flowchart of one embodiment of using the bookmark functionality. At block 1535, the user connects to the IIM. At block 1540, the user requests access to the user's bookmarks through the IIM user interface. For one embodiment, the user requests the bookmarks by pressing the "Tags" button on the user interface.

At block 1545, the IIM generates a bookmark list from the user's bookmark database, and sends the list to the client browser to display. For one embodiment, the bookmark list is displayed in the destination server display area. For another embodiment, the bookmark list is displayed in a separate window, or a separate frame.

At block 1550, the user selects a bookmark to access a destination server page.

At block 1555, the IIM fetches the page address corresponding to the selected bookmark from the bookmark database. The bookmark database includes the actual address of the bookmark.

At block 1560, the destination server page is fetched by the IIM. The data from the destination server is instrumented and is sent to the client browser for display. In

this way, the user can access bookmarks stored in the IIM's bookmark database. The process then continues to block 1565, and ends.

Figure 15C is a flowchart of one embodiment of using the history functionality. At block 1570, the user connects to the IIM.

At block 1575, the user requests access to the history list through the IIM user interface. The history list includes the sites the user previously visited. For one embodiment, the history list is maintained for only a period of time, such as thirty days. For another embodiment, the history list is maintained indefinitely, and may be purged by the user.

At block 1580, the IIM generates a history list from the user's history database, and sends the history list to the client browser for display. For one embodiment, the history list is displayed in the destination server display area. For another embodiment, the history list is displayed in a separate window, or a separate frame

At block 1582, the user selects a list entry to access the destination server page. At block 1585, the IIM fetches the page address from the history database. The page address is referenced through the IIM.

At block 1590, the IIM fetches the destination server page, instruments the communication, and sends the data to the client browser for display. At block 1595, the process ends. In this way, the IIM permits a user to access a variety of services through the IIM.

Figures 16A-C show sample alterations of references from the destination server by the IIM. Figures 16A-C illustrate changes to HTML, HTTP protocol, JavaScript, and Java. For one embodiment, this technique may be expanded to new languages and other types of interfaces. The data that is normally communicated directly between a Destination Server (DS) and client browser is altered by the IIM, as shown by Figures 16A-C. For one embodiment, some data may be transmitted directly between the DS and the client browser, without passing through the IIM.

For one embodiment, the IIM performs a subset of the message modifications required for redirection and downloads the client component to the client's browser, which performs the remaining subset of message modifications on the client machine.

Together these two subsets of message modifications provide a complete solution for using an independent intermediary mechanism between a client and a server.

The modification of HTTP communication messages for redirection occurs on both the IIM and the client browser using the client component. The points at which the message modifications occur are called "HTTP control points".

Figures 16A-C illustrate examples of HTTP control points that occur on the client browser and the IIM. For HTTP message documents, description of modification code covers the three programming languages that are most widely used today for HTTP communication: HTML, JavaScript and Java. For another embodiment, the IIM utility may be broadened to include HTTP control points in other programming languages used for HTTP message documents. For one embodiment, the protocol modified in the messages is defined by the HTTP specification standard. One skilled in the art would understand how to expand the technique described to different programming languages or message protocols.

Figure 17 is a table illustrating examples of making the IIM user interface frame persistent. The IIM prevents DS's from overwriting the user interface of the IIM. This permits the user to access the IIM regardless of what DS he or she is accessing.

Figure 18 is a table illustrating examples of accessing cookies from the IIM. Generally, the destination server and destination server data on the client system access the cookie cache on the client's computer system. The IIM modifies the access mechanisms to access cookies from the IIMs cookie database.

Figure 19 is a table illustrating examples of preserving top frame or IIM frame integrity for DS. Objects are often hung from the top frame of the client browser. The IIM changes the references to the top frame to create or access these objects to references to the top frame of DSDA. In this way, the objects are appropriately handled.

Figures 16-19 list some sample alterations resulting from the code instrumenting described above. Alternative methods of altering the code may be used. One skilled in the art knows how to implement different changes.

In the foregoing specification, the invention has been described with reference to specific exemplary embodiments thereof. It will, however, be evident that various modifications and changes may be made thereto without departing from the broader

spirit and scope of the invention as set forth in the appended claims. The specification and drawings are, accordingly, to be regarded in an illustrative rather than a restrictive sense.

CLAIMS

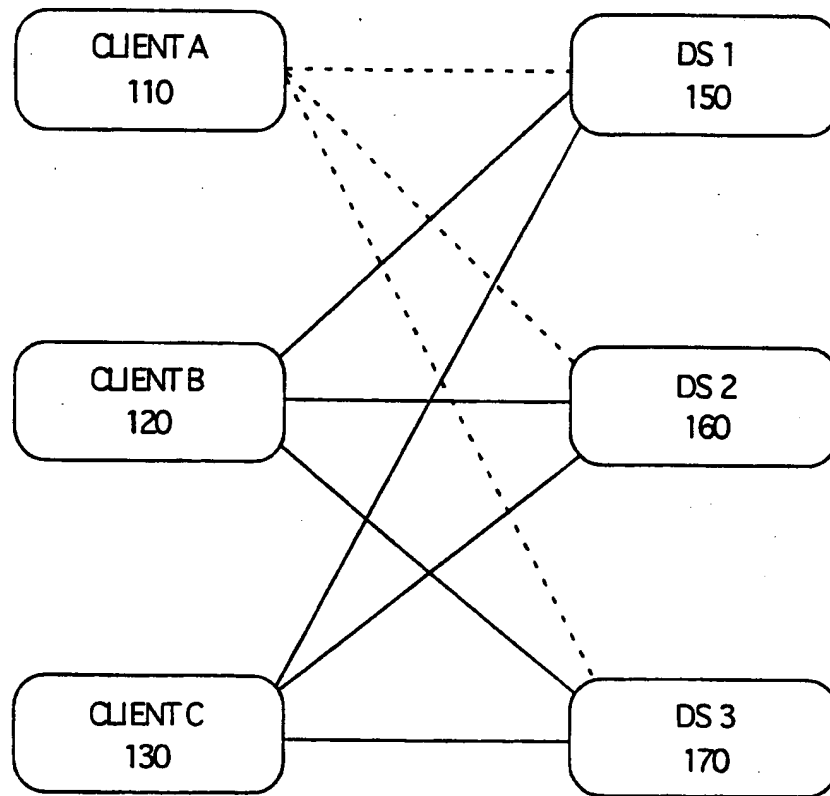

What is claimed is:

1. A method of accessing data through an independent intermediary mechanism (IIM), the method comprising:
 - displaying a frame including a user interface of the IIM, the frame framing a destination server display area (DSDA);
 - retrieving destination server data (DS data) for display from a destination server;
 - instrumenting the DS data prior to display such that future data retrieved from the destination server is displayed in the DSDA, without writing over the frame displaying the user interface of the IIM.
2. The method of claim 1, further comprising:
 - altering requests for cookies such that cookies relevant to the destination server are accessed from the IIM.
3. The method of claim 1, further comprising:
 - determining if a user's portion of the IIM includes a cookie for the destination server, and serving the cookie to the destination server and to the DS data, if the user's portion includes the cookie.
4. The method of claim 3, further comprising determining if a browser includes the cookie, and if the browser includes the cookie:
 - serving the cookie to the destination server and the DS data; and
 - saving the cookie in the user's portion of the IIM.
5. The method of claim 2, wherein cookies received from the destination server or created by the DS data are stored in a user's portion of the IIM.
6. The method of claim 1, wherein at least one reference in the DS data to other DS data is redirected through the IIM.
7. The method of claim 1, wherein the step of instrumenting data prior to display comprises replacing a reference to a top frame or IIM frame with a reference to a top of the DSDA.
8. The method of claim 7, wherein said step of replacing comprises,
 - in HTML, determining if a value of a Target attribute is "_top", and changing the value to represent a topmost area of the DSDA.

9. The method of claim 7, wherein said step of replacing comprises, in Java, determining if a value of a Target attribute is "_top", and changing the value to represent a topmost area of the DSDA.
10. The method of claim 7, wherein said step of replacing comprises, in JavaScript, replacing the reference to "top" with a reference to a topmost area of the DSDA.
11. The method of claim 6, wherein for predefined JavaScript, HTML and other code, the step of instrumenting is performed on a server side of the IIM, and wherein for dynamically generated code, the step of instrumenting is performed on a client side of the IIM.
12. The method of claim 1, wherein the step of altering data prior to display comprises replacing the DS data references to a reference through the IIM.
13. The method of claim 12, wherein only selected references are routed through the IIM.
14. The method of claim 12, wherein said step of replacing comprises altering a language of the reference such that any parameter which when set causes a document to be fetched from the destination server causes the document to be fetched through the IIM.
15. The method of claim 1, wherein links and references invoked by a user's selection are altered when the user selects the reference.
16. A method of accessing data through an independent intermediary mechanism (IIM), the method comprising:
 - retrieving destination server data (DS data) for display from a destination server;
 - instrumenting the DS data such that future data retrieved from the destination server is retrieved through the IIM.
17. A method of accessing data through an independent intermediary mechanism (IIM), the method comprising:
 - retrieving destination server data (DS data) for display from a destination server;
 - altering a request for a cookie from the destination server or the DS data, such that the cookie relevant to the destination server is accessed from the IIM; and
 - storing and updating the cookie in the IIM cookie database.

18. An independent intermediary mechanism (IIM) comprising:
a core engine retrieving destination server data (DS data) for display from a destination server;
a user interface framework for maintaining a frame including the IIM user interface on a client browser as the client browser accesses different destination servers;
19. The IIM of claim 18, further comprising:
a cookie database;
a cookie modification engine that alters a request for a cookie from the destination server or the DS data, such that the cookie relevant to the destination server is accessed from the IIM cookie database; and
the cookie modification engine further for maintaining and updating the cookie.
20. The IIM of claim 18, further comprising:
a data modification engine for instrumenting the DS data such that future data retrieved from the destination server is retrieved through the IIM.
21. A communications mechanism comprising:
a first independent intermediary mechanism (IIM) displaying a frame including a user interface of the IIM, the frame framing a destination server display area (DSDA);
the first IIM retrieving destination server data (DS data) for display from a destination server and instrumenting the DS data prior to, the first IIM further for providing services to the user.

PERSONALIZED ACCESS TO WEB SITES

Background of the Invention5 1. *Field of the Invention*

 This invention relates to web access; to summarization and aggregation of personalized information, such as used in conjunction with an internetworking environment; and to structured data input and automatic form processing, such as used with the world wide web (including wireless uses).

102. *Related Art*

I.

15 One aspect of the internet which has become popular is access to the world wide web, in particular, access by web client devices or software to information provided by web servers (also known as "web sites"). Some of these web sites provide information or services only to a set of users (operators of web clients) to which access is restricted, or provide information that is personalized to registered users. For a first example, users may be required to register, to identify themselves at connection to the web site, and to authenticate themselves to the satisfaction of the web site, before the web site grants that user access to certain information or services. For a second example, users may be required to identify and authenticate themselves before the web site provides information personalized to that user, such as information likely to be of particular interest to that user. For a third example, some web sites allow unrestricted access to a first set of public information, and only restricted access to a second set of restricted information.

20
25

 As the number of such web sites becomes relatively larger, a first problem in the known art is management of information relating to those web sites, including access parameters and authentication information (such as passwords). For example, the user might be required to maintain (either offline or online) information regarding each such web site, including authentication information (such as a user name and password, a digital certificate, or a hardware address) that may differ for different web sites.

30

Some attempts have been made in the known art to address this problem, such as software that maintains records of authentication information for different web sites, or by maintaining the information in "cookies" (data objects) recorded at the web client. These
5 known methods are subject to several drawbacks. First, it is difficult to use the same web site from different physical web client device, and is also difficult to distinguish among different users of a single web site all using the same physical web client device. Second, the use of "cookies" or other data objects recorded at the web client device (such as a laptop or workstation) implies that any user who has physical control of the device will have access to
10 the web sites.

Accordingly, it would be advantageous to provide a technique in which a user can maintain authentication information (such as a user name and password) for multiple different web sites, and be able to access those different web sites using a single set of
15 authentication information.

A second problem in the known art is that it is inconvenient to re-enter or update the information for multiple web sites, particularly when the number of web sites becomes relatively large. Some attempts have been made in the known art to address this
20 problem, such as software that maintains records of authentication or demographic information and attempts to interact automatically with the web site requesting the information. These known methods are subject to the drawback that different web sites can and often do request similar information in quite different formats. Moreover, it would be advantageous for a single user to be able to select from multiple profiles for use with different
25 web sites, so as to personalize the information obtained from that web site, or so as to discourage dissemination of personal information.

A third problem in the known art is that a first user may desire to allow a second user temporary access to the first user's registered account at a selected web site.
30 Using known techniques for authentication, such as a user name and password, the first user cannot assure any limitations on the second user's temporary access. Most servers would even allow the second user to change the associated password, and thus deny future access to the first user. An aspect of this problem is that the first user might desire to grant only

restricted access rights to the second user, so as to restrict the second user from performing banking or commercial transactions using the first user's account.

5 A fourth problem in the known art is that each such web site will often request an email address from the user, so as to send advertisements and possibly other "junk" email to the user. This can become a nuisance when the user is registered with multiple web sites. It would be advantageous if the user could separate out email from web sites, so as to be able to control email from those web sites. For example, the user could desire to treat differently email that is not sent automatically (and thus is more likely to be of real interest to the user).

10

Accordingly, it would be desirable to provide an improved technique for access to personalized web sites. A first aspect of the invention is that a user can maintain and select from a set of multiple profiles for use with a selected web site. This can aid the user in presenting only desired information to the selected web site. A second aspect of the invention is that a user can maintain a single set of authentication information for access to multiple restricted web sites, along with bookmark information for the web site, for access from additional locations. A third aspect of the invention is that a first user can allow a second user (or a set of such second users) temporary access to a set of web sites, possibly with the temporary access restricted to a subset of the information or services offered by those web sites. A fourth aspect of the invention is that the user can separate out and treat differently email from those web sites. This can aid the user in filtering out unwanted email.

20

II.

One aspect of the internet which has become popular is access to the world wide web, in particular, access by web client devices or software to information provided by web servers (also known as "web sites"). Individual users, using web client software, request information from web sites and receive information in response to those requests. Each web site can include information in a variety of forms, including text, other media, and links, which are delivered for presentation to the user. The user can follow the links to other and further web sites, in a process sometimes called web "surfing."

30

One problem in the known art is that individual users perform web surfing without reference to other individual users. Although it is possible for multiple users to

access the same web site at once, there is no convenient and simple technique in the known art for those users to coordinate following links to other and further web sites. Similarly, there is no convenient and simple technique in the known art for providing, for a group of related users, simultaneous access to a sequence of web sites.

5

Accordingly, it would be desirable to provide an improved technique for group access to web sites. This is achieved in an embodiment of the invention in which multiple related users can simultaneously access a sequence of web sites (web surfing), such that each of the related users has substantially the same content presented at the same times. In a first
10 embodiment, a selected one of the related users controls the web surfing process. In a second embodiment, a selected plurality of the users collectively control the web surfing process.

III.

One aspect of the Internet which has become popular is access to World Wide
15 Web, in particular, access by web client devices or software to information provided by web servers (also known as "web sites"). Individual users, using web client software, request information from web sites and receive information in response to those requests. Each web site can include information in a variety of forms, including text, other media, and links, which are delivered for presentation to the user. The user can follow the links to other and
20 further web sites, in a process sometimes called web "surfing."

One problem in the known art is that individual users develop a substantial amount of personalized information, stored at different web sites in different formats, and with differing methods of access. Although it is possible for an individual user to retrieve and
25 aggregate that individual's personalized information from a plurality of web sites, there is no convenient and simple technique in the known art to do so. Rather, it typically takes significant time navigating differing data formats and methods of access imposed by different web sites.

30 Accordingly, it would be desirable to provide an improved technique for summarization and aggregation of personalized information. This is achieved in an embodiment of the invention in which a personal data server obtains personalized information for individual users, on their behalf, from one or more web sites having that information, and

presents that personalized information to those individual users in a convenient format. The convenient format can include a technique for presentation that allows aggregation, modification, or summarization.

5 The invention provides an enabling technology for summarization and aggregation of personalized information, to obtain substantial advantages and capabilities that are novel and non-obvious in view of the known art. Examples described below relate to information for electronic commerce ("e-commerce"), but the invention is broadly applicable to many different types of personalized information or transactions.

10

IV.

One aspect of the Internet that has become popular is access to the world wide web, in particular access by web client devices or software (also known as "web browsers") to information provided by web servers (also known as "web sites"). Some of these web sites
15 provide structured forms for data input, such as HTML or XML forms, table entry of data, and other techniques. These structured forms for data input can be used for a variety of data-capture purposes. Some examples could include registration of a new user, adding a product to a "shopping cart" or other electronic commerce technique, and purchasing a product (or purchasing a set of products already identified using a shopping cart).

20

One problem in the known art is that entering data for such forms is repetitive and relatively uninteresting for the human user. This takes unnecessary time away from other activities the user could be performing. It can present a barrier to web site usage, and can also present a barrier to effective sales and rapid order fulfillment.

25

Another problem in the known art is that it is not practical to complete manual data entry for such activities when the user is accessing the internet through a small-screen device or a bandwidth constrained network, such as in wireless internet access.

30

One known method is to record information for such forms logically local to the user's web client, such as on the user's computer in the form of a "cookie" or other structured data. While this method generally achieves the objective of allowing the user to repeatedly use a web site without having to re-enter the same information, it is subject to

several drawbacks. First, it is generally inapplicable when the user is presented with a request for data input from a new web site, as that new web site does not retrieve the relevant information from the cookie. Second, it is generally inapplicable when a user is accessing the web site from more than one client device. Third, the relatively weak security associated with cookies militates against storing confidential information, such as credit card information.

A second known method is the "One Click shopping" method available at the web site "amazon.com," in which allows automation of transactions for all users at the specific web site. While this method generally achieves the objective of allowing the user to repeatedly use a web site without having to re-enter the same information, it is subject to the drawback that it works only with those specific web sites that have directly linked their server software with the One Click shopping server software and database.

Accordingly, it would be advantageous to provide a technique for automatically completing such forms, without having to obtain input from a human user regarding what information properly belongs in which fields of the form, that is not subject to drawbacks of the known art.

Summary of the Invention

I.

The invention provides a method and system for access to personalized web sites. In a first aspect of the invention, a user can maintain and select from a set of multiple profiles for use with a selected web site. In a second aspect of the invention, a user can maintain a single set of authentication information for access to multiple restricted web sites, along with bookmark information for the web site, for access from additional locations. In a preferred embodiment, the user can use the single set of authentication information to manage multiple restricted web sites, including monitoring usage of cost-based services and being able to control or provide automated renewal of such services. In a third aspect of the invention, a first user can allow a second user (or a set of such second users) temporary access to a set of web sites, possibly with the temporary access restricted to a subset of the information or services offered by those web sites. In a fourth aspect of the invention, the user can separate out and treat differently email from those web sites.

II.

The invention provides an improved technique for group access to web sites. Multiple related users can simultaneously access a sequence of web sites, such that each of the related users has substantially the same content presented at the same times. In a first embodiment, a selected one of the related users controls the web surfing process. In a second embodiment, a selected plurality of the users collectively control the web surfing process. In a first aspect of the invention, the group surfing process can be used in conjunction with a communication technique between and among groups of users involved in the web surfing process, such as telephone communication, voice over IP, or Internet chat. In a second aspect of the invention, the group surfing process can be used in conjunction with other network functions, such as electronic commerce, on-line or otherwise remote training, virtual displays or tours, telemedicine or other process telecontrol, or consulting (such as in the fields of finance, advertising or marketing). More generally, the group surfing process can be used in conjunction with functions that could otherwise occur on display before an in-person audience.

III.

The invention provides an improved technique for summarization and aggregation of personalized information. A personal data server obtains personalized information for individual users, on their behalf, from one or more web sites having that information, and presents that personalized information to those individual users in a convenient format. The convenient format can include a technique for presentation that allows aggregation, modification, or summarization.

25

In a first aspect of the invention, the personal data server maintains information for a set of individual users so as to be able to retrieve, on their behalf, personalized information from one or more web sites having that information. The personal data server presents that personalized information in a dynamically generated "jump page" that the individual user can peruse and use to navigate directly to one or more web sites having that information at hand. The personal data server also aggregates or summarizes that information so that the individual user can view a more global presentation without having to individually navigate to each web site having personalized information about or selected by that individual

user. The aspect has broad applicability to e-commerce and electronic banking, to inter-user communication, and to inter-user interest groups.

In a second aspect of the invention, the personal data server can be used to
5 provide only limited or only aggregate access to personalized information to persons or
entities other than the individual for which the information is personal. The personal data
server can collect information approved for collection by a set of individual users, aggregate
or summarize that information, and present only the aggregate or summary to a reviewing
person or entity. This aspect has broad applicability to census and polling data, market
10 surveys and other data collection, and to inter-user communication.

IV.

The invention provides a method and system for automated and intelligent
structured data input. A user operating a web browser to access a web site is assisted by
15 personalization software that identifies forms for structured data input and assists the user
with data input. In a preferred embodiment, operations described herein can be performed
automatically on the personalization server (or other server) on behalf of the user.

In a first aspect of the invention, the personalization software, when possible,
20 associates each set of descriptive text with a logical field value, when possible associates
screen locations for each relevant input field with a logical field value, and when possible
associates logical field values with multiple data values or partial data values. Having
associated logical field values for each relevant input field, the personalization software
provides data input for those fields without substantial requirement for user data input, and
25 when operating on the server, is capable of returning the appropriate data to the third party
web site. In a preferred embodiment, the data input for those fields can include pre-recorded
personal information about the user, such as pre-recorded data for the user's name, address,
telephone number, credit card information, demographic information, and preferred login
name or password. This first aspect of the invention has applicable uses including automatic
30 registration of a user at a new web site, automatic login using the login page of a web site, and
form filling for checking out purchases from multiple web sites.

In a second aspect of the invention, the personalization software uses a "meta-bookmark," which links an identifier of a web page (such as a URL) and an association of that web site location with a script or program fragment to be executed for that web page to send appropriate information to the personalization server. The meta-bookmark thus allows the personalization software to either (a) complete the transaction on that server, or (b) send back the appropriate information to the client so the transaction can be completed on the client while keeping most confidential and other data on the personalization server. The personalization software is thus able to perform a plurality of actions with regard to the web page (and with regard to successor web pages), including entering data into forms, checking that data against a confirmation page, and confirming that the data received by the web site is correct. This second aspect of the invention has applicable uses including automatic performance of an e-commerce operation, such as supplying credit card information and confirming an e-commerce transaction.

In a third aspect of the invention, a helper application assists the personalization software in recognizing differing types of structured data forms and is directed by the personalization software for entering data for those differing types of structured data forms. For example, the helper application can determine differences between a web page for new-user registration, a web page for user login, and a web page for confirming an e-commerce transaction, and can complete these pages directly without substantial assistance from the user, using information from the personalization software.

In a fourth aspect of the invention, the personalization software performs automated new-user registration for the user of the web client at a plurality of web sites. Personalization information is collected for the user and sent to each web site in the individual format that web site requests. If one or more web sites request further personalization information not already entered by the user, the personalization software can request that further personalization information at once, so as to send it to those one or more web sites.

In a fifth aspect of the invention, the personalization server automates the checkout process for purchases on many different Web sites, automatically processing the multiple web pages required by each shopping store independently, and successively

completing each of them with the purchasing agent and using the relevant user information it has on hand.

The invention provides an enabling technology for a wide variety of applications for structured data input, and for automated or intelligent access to logically remote information requesters. Examples described below relate to personalized web sites and to e-commerce, but the invention is broadly applicable to many different types of information exchange, including many different types of information transactions and interactions between and among communicating computers and to computer software.

Detailed Description of the Preferred Embodiment

In the following description, a preferred embodiment of the invention is described with regard to preferred process steps and data structures. Those skilled in the art would recognize after perusal of this application that embodiments of the invention can be implemented using one or more general purpose processors or special purpose processors or other circuits adapted to particular process steps and data structures described herein, and that implementation of the process steps and data structures described herein would not require undue experimentation or further invention.

I.

System Elements

Figure 1 shows a block diagram of a system for access to personalized web sites.

5 A system 100 includes at least one web client 110, a communication network 120, at least one web site 130, and a personalization server 140.

As used herein, the terms "client" and "server" refer to client-server relationships between client and server, not necessarily to particular physical devices.

10

As used herein, the phrase "web client" includes any combination of devices or software taking on the role of a client in a client-server environment in the internet, the world wide web, or an equivalent or extension thereof. There is no particular requirement that the web clients 110 must be individual devices; they can each be a single device, a set of
15 cooperating devices, a portion of a device, or some combination thereof (such as for example a device providing web server services that acts as an agent of the user).

As used herein, the phrase "web site" includes any combination of devices or software taking on the role of a server in a client-server environment in the internet, the world
20 wide web, or an equivalent or extension thereof. There is no particular requirement that the web sites 130 must be individual devices; they can each be a single device, a set of cooperating devices, a portion of a device, or some combination thereof.

The web client 110 includes a processor operating under control of web client
25 software 111, such as a web browser, and disposed for use by an operator or user 112. In a preferred embodiment, the web client software 111 includes software 113 disposed for communicating with the web sites 130 using a communication protocol, possibly including data 114 stored locally at the web client 110 regarding those web sites 130.

30 In a preferred embodiment, the web client 110 includes a general-purpose computer, such as a laptop or workstation. However, the web client 110 can also include (either alone or in conjunction with a laptop or workstation), a hand-held calendar (such as a "Palm Pilot" or other hand-held device), a portable computer, a special purpose computer, a

cellular telephone or other telephonic device, a telephone system with interactive voice response, or a web server acting as the agent for an user. In alternative embodiments, the web client 110 may also include any other device disposed for performing the all or some functions described herein. The location, the type of device, and the nature of the connection
5 of the web client 110 to the web site 130 can each differ between pairs of connection sessions between the web client 110 and the web site 130.

In a preferred embodiment, the communication network 120 includes a packet switched network such as the Internet, as well as (in conjunction with or instead of) an
10 intranet, an enterprise network, an extranet, a virtual private network, a virtual switched network. In alternative embodiments, the communication network 120 may include any other set of communication links that couple the web client 110, web site 130, and personalization server 140 so they can perform the functions described herein.

The communication network 120 is disposed for transporting messages 151
15 between any two of the web client 110, the web site 130, and the personalization server 140. The messages 151 are formatted in the communication protocol recognized by the web client 110, the web site 130, and the personalization server 140. In a preferred embodiment, the communication protocol includes HTTP (hypertext transfer protocol) or a variant thereof,
20 such as SHTTP (secure HTTP). The communication protocol can also include other protocols for requesting and sending information, including FTP (file transfer protocol), Gopher, and variants thereof. Although the description refers herein primarily to HTTP, those of ordinary skill in the art will recognize, after perusing this application, that use of the invention with other protocols would not require new invention or undue experimentation.

25 In a preferred embodiment, those messages 151 that request information can include an identifier 152 for a requested page 153. The page 153 includes a set of information, possibly including data in one of a number of formats, and possibly also includes a number of links 154 to other pages 153. Each link 154 includes an identifier 152 for its
30 target page 153, and information about the target page 153 (such as a title).

In a preferred embodiment in which the communication protocol includes HTTP or a variant thereof, each page 153 can include data in the form of text, images (still or

animated), sound, program fragments (such as applets, applications, or JavaScript), or combinations thereof.

In a preferred embodiment, the web site 130 includes a processor operating
5 under control of web server software 131, and disposed for delivering information 132 to the
web client 110 in response to requests made using the communication protocol. In a preferred
embodiment, the web site 130 includes software 133 disposed for communicating with the
web client 110 using the communication protocol, and includes authentication or
personalization data 114 (or techniques) stored locally at the web server 130 regarding those
10 web clients 110.

In a preferred embodiment, the personalization server 140 includes a processor
operating under control of personalization software 141, disposed for performing the
functions described herein, including maintaining information 142 about relationships
15 between the web client 110 (or a user thereof) and the web site 130. In a preferred
embodiment, the personalization software 141 includes software 143 disposed for
communicating with the web clients 110 and the web sites 130 using the communication
protocol, and includes an authentication and personalization database 144 stored locally at (or
otherwise accessible by) the personalization software 141, regarding those web clients 110
20 and web sites 130.

Interactions between System Elements

The web client software 111 is disposed for sending a message 151 to the
25 personalization server 140, to request the personalization server 140 to respond and perform
functions described herein. In a preferred embodiment, the message 151 is responsive to an
action by the user of the web client software 111, such as by selecting a web page or a link to
a web page.

30 The personalization software 141 is disposed for receiving the first message
151 from the web client software 111. The personalization software 141 uses information in
the first message 151 from the web client software 111 to navigate to the selected web site
and to identify and authenticate the user at the selected web site. The personalization

software 141 can perform these functions in one or more, or a combination of, the following ways:

- o The personalization software 141 can send a second message 151 to the web site 130,
5 to request the web site 130 to respond and perform functions described herein.

When using this first method, the personalization software 141 communicates directly with the web site 130, so as to identify and authenticate the user.

- 10 When using this first method, the web server software 131 is disposed for receiving the second message 151 from the personalization software 141, and for responding thereto. After proper identification and authentication, the web server 131 sends further messages 151 directly to the web client 110 using the network 120.

- 15 o The personalization software 141 can send additional information (such as parameters in an HTTP message 151) to direct the web client software 111 to perform functions as described herein.

- 20 When using this second method, web client software 111 (using the additional information) directly requests appropriate information (such as a login or registration form) from the web site, and to respond with appropriate information to identify and authenticate the user (such as to respond with a completed registration form).

- 25 When using this second method, the personalization software 141 preferably supplies the additional information for the web client software 111 in an encrypted or otherwise encoded form, so that the user of the web client software 111 does not obtain identification and authentication information directly. Encryption also provides additional security while sending messages 151 across the network 120.

- 30 The functions for the web site 130 are not substantially different from those performed by the web site 130 in response to similar requests from others, including possibly the web client software 111. Accordingly, there is no particular requirement that the web

server 130 be modified to operate in conjunction with the web client software 111 and the personalization server 140 to perform the functions described herein.

After registration is accomplished, the web server software 131 can respond
5 either directly to the personalization server 140 (with a third message 151) or directly to the web client 110 (with a fourth message 151), as directed by the personalization software 141.

Registering the User with the Personalization Server

10 The personalization server 140 is disposed to maintain authentication and personalization information about the user at the web client 110, to record that information in its database 144, and to communicate (directly or indirectly) with the web site 130 regarding that information.

15 When the user at the web client 110 wishes to register with the personalization server 140, the web client software 111 sends a message 151 to the personalization server 140 requesting a registration page 153. The personalization server 140 sends the registration page 153 to the web client software 111, which presents the registration page 153 to the user.

20 The registration page 153 includes a form, applet, or other structure for gathering information from the user. In this way, the personalization server 140 requests authentication and personalization information about the user. Upon receiving that information, the personalization server 140 records it in its database 144. Although the personalization server 140 records information about the user at first registration of that user
25 with the personalization server 140, the user can at other and further times add or modify that information, or add or modify profiles for use with web sites 130, independent of actual use of any selected web site 130.

In a preferred embodiment, the authentication and personalization information
30 about the user includes a username and a password. Methods of username and password authentication are known in the art of computer security. In alternative embodiments, the personalization server 140 may use other and further authentication techniques in addition to or instead of username and password authentication. These other and further authentication

techniques can include any one of, or some combination of, identification using the following:
software identification such as digital certificates or other digital encryption techniques,
hardware identification such as processor identification information, "smart" cards,
communication link authentication such as digital or analog telephone subscriber line
5 identification information, or other known methods for identification or authentication. In
preferred embodiments, authentication techniques can be associated with selected degrees of
user access, so that greater or lesser authentication controls are placed on greater or lesser user
access capabilities.

10 *Registering At A New Web Site*

The personalization server 140 is also disposed to maintain, in its database
144, information about the user at the web client 110. This information is preferably recorded
as one or more selectable profile for the user, so that the user can select one such profile for
15 communication, identification and personalization for one or more selected web sites 130.

When the user at the web client 110 wishes to register (and thus identify)
themselves at a new web site 130, the web client 110 contacts the web site 130 in one of two
ways:

20

- o The user at the web client 110 contacts the web site 130 directly using the web client
software 111.

25

When this first technique is used, the user at the web client 110 provides an identifier
152 (such as a URL) for an registration page 153 at the web site 130 to the
personalization server 140. The user can use an additional command for the web
client 110, or can execute an applet or complete a dialog box supplied by the
personalization server 140. With this information, the personalization software 141
performs registration using a profile selected by the user at the web client 110.

30

- o The user at the web client 110 identifies a location (such as a URL) for the web site
130 to the personalization server 140. The personalization server 140 contacts the

web site 130 in place of the user, as if the user had contacted the web site 130 directly using the web client software 111.

5 When this second technique is used, the personalization software 141 recognizes the registration page 153 at the web site 130 and performs registration using a profile selected by the user at the web client 110.

10 In a preferred embodiment, the personalization software 141 automatically completes the registration form 131 using any appropriate automated technique, such as known pattern matching, neural network, genetic algorithms, other techniques, or some combination thereof, to match names of requested form data fields with available profile data fields.

15 In a preferred embodiment, the user at the web client 110 can designate none, some, or all of the information fields in the selected profile by as confidential. If an information field is designated confidential, the personalization software 141 asks the user to confirm that the user wishes to provide that information before sending it to the web site 130.

20 The personalization server 140 is also disposed to maintain information about the web site 130, to record that information in its database 144, and to communicate with the web site 130 in response to that information.

25 It can occur that the user at the web client 110 will need to complete the profile by adding further information. In such cases, the personalization server 140 completes the registration form accordingly if the user so directs. The personalization server 140 also updates its database 144 accordingly if the user so directs. Depending upon service management choices, the personalization server 140 can update some, all, or a group of profiles selected by the user.

30 When the user at the web client 110 wishes to register with a new web site 130, the web client software 111 sends a message 151 to the personalization server 140 with an identifier 152 for an authentication page 153 at the web site 130. The web client software 111 requests that the personalization server 140 register the user at that web site 130.

In response, the personalization server 140 sends a message 150 to the web site 130 identifying the registration page 153. The personalization server 140 uses the profile information about the user at the web client 110, from its database 144, to respond to the web site 130 with information requested by the web site 130 for personalization.

The personalization server 140 generates authentication information (such as a password) and records that authentication information in its database 144 in association with the user at the web client 110. For those web sites 130 that send an email message or other message back to the web client 110 with a site-selected password, the personalization server 140 intercepts that message and records the site-selected password in its database 144.

As part of authentication with a new web site, the personalization server 140 causes any links or forms 154 identified to the web site 130 to point back to pages 153 at the personalization server 140, not the web client 110. Moreover, the personalization server 140 can optionally (upon user instruction or otherwise) generate a unique email address for the web site 130 to identify the user at the web client 110. If so, the unique email address is given to the web site 130 instead of any regular email address at which the user might receive email.

The personalization server 140 records any necessary identification and authentication information for the user, so that the personalization server 140 can automatically authenticate the user at the web site 130, upon receiving a request to do so from the web client 110.

25 Selecting (and Logging Into) the Web Site

When the user at the web client 110 wishes to identify (and authenticate) themselves to a already-registered web site 130, the web client software 111 sends a message 151 to the personalization server 140 with an identifier 152 for a selection page 153 at the personalization server 140. The selection page 153 preferably includes information about each of the web sites 130 (and services offered thereat) at which the user has registered. In alternative embodiments, the selection page 153 can include links to additional and further selection pages 153, or can have a hierarchical or other format in other ways.

The personalization server 140 provides or dynamically generates the selection page 153 in response to information in the database 144 regarding the user, and in response to information in the database 144 regarding the web site 130. In a first preferred embodiment, 5 the selection page 153 can be stored and updated at times selected by the personalization server 140 or the user, or can be dynamically generated at user direction. The selection page 153 preferably includes an identifier (such as a name) for each registered web site 130, along with possibly other information:

- 10 o information regarding use of the web site 130, such as a last use, frequency of use, or last page 153 requested from that web site 130;
- o information regarding commercial aspects of the web site 130, such as whether the web site 130 is fee-based, or whether the user's registration at the web site 130 is 15 about to expire (or has expired and could be renewed);

and

- o usage or other information provided by the web site 130 and aggregated by the personalization server 140.

20

The user can select one or more of the web sites 130 identified on the selection page 153 for connection. In response thereto, the personalization server 140 connects to each selected web site 130 and re-authenticates the user to that selected web site 130. In a preferred embodiment, personalization server 140 sends any identification and authentication 25 information (such as a password) in an encrypted format. A secondary user with restricted access (as described below) thus cannot obtain unrestricted access to the web site 130 and services.

In alternative embodiments, the personalization server 140 sends the 30 identification and authentication information (such as a password) in an encrypted format to an applet or plug-in at the web client 110. The web client 110 invokes the applet or plug-in with the encrypted information to automatically identify and authenticate the user with the web site 130.

In a preferred embodiment, the personalization server 140 maintains information about bookmarks, "favorites," viewed pages, or other important web sites 130 in its database 144, in association with the user. This allows the user to send a collection of
5 bookmarks from a restricted web site 130 to a secondary user with restricted access (as described below). This information can also be used by the web client 110 to display those pages available at the web site 130 without having to actually having to re-register at the web site 130. This allows the user to access bookmark information for restricted web sites 130 from any web client 110, whether or not web client 110 has the appropriate bookmark stored
10 locally.

Using the Selected Web Site(s)

Upon or before authentication with the selected web site(s) 130, the web client
15 software 111 can communicate directly with the web site software 131 to request and receive information. The user is thus able to maintain a single set of authentication information for access to multiple restricted web sites.

In a preferred embodiment, the user can use the single set of authentication
20 information to manage multiple restricted web sites, such as monitoring usage of cost-based services and being able to control or provide automated renewal of such services. For example, the user can order the personalization server 140 (and the personalization server 140 can respond to such orders) to perform the following services:

- 25 o automatic reminder of web sites 130 for which registration must be periodically renewed;
- o automatic renewal of registration at web sites 130 for which registration must be periodically renewed;
- 30 and
- o automatic de-registration from web sites 130 for which registration might be automatically renewed, but for which the user has no further interest.

Use by Secondary Users

A first user can also request the personalization server 140 to allow a second
5 user, possibly using the same web client 110 or possibly using a different web client 110, to
access those web sites 130 for which the first user is registered.

The personalization server 140 records information about those second users,
including the scope of access they are permitted, in the database 144. The scope of access
10 permitted to those second users can be limited in at least the following ways:

- o limitation to selected web sites 130 or selected classes of web sites 130;
 - o limitation to selected services or selected classes of services;
 - 15 o limitation to selected times or dates, or combinations thereof, whether once-only or
periodically;
 - o limitation to selected amounts of resources or services;
 - 20 o limitation to selected numbers of such second users.
- or
- o limitation to read-only operations by such second users.

25 When one of those second users wishes to use the selected web sites 130, the
second user requests the personalization server 140 to identify (and authenticate) themselves
to the web site 130 as the first user. Thus, the web site 130 is deceived into believing that the
second user is the true registered user. The personalization server 140, in response to the
30 request and in response to the database 144, identifies (and authenticates) the second user to
the web site 130 using the same information as the first user, while hiding authentication or
other account information from the second user (such as a password).

In response to the database 144, the personalization server 140 can require that it mediates the second user's access to the web site 130, by requiring that all requests for information by the second user must first pass through the personalization server 140. This allows the personalization server 140 to perform one or more, or a combination of, the following:

- o prevent the web site 130 from sending cookies to the second user;
- o disable the second user from changing information for the first user's account at the web site 130;

and

- o restrict the second user to limited access, such as read-only access.

15 *Email Usage*

As noted above, the personalization server 140 generates a new email address for the first user when first identifying and authenticating that first user to a new web site 130. The personalization server 140 can accordingly restrict or partially restrict access by the second user to email received for that email address at the personalization server 140. (In a preferred embodiment, the second user is given no access to email for the first user.)

The personalization server 140 provides web-based access to any email received for that email address from the web site 130. As part of this web-based access, the user at the web client 110 can request the personalization server 140 to perform the following services:

- o forwarding selected email to a selected target email address;
- o deleting or ignoring selected email for one of the web-site specific email addresses (with the result that selected email from any particular web site or associated service can be deleted or ignored);

- o presenting selected email for one of the web-site specific email addresses using the web client software 111;
- or
- 5 o providing the user of the web client software 111 with the ability to respond to selected email.

System Operation

10 Figure 2 shows a process flow diagram for a method of using a system for access to personalized web sites.

A method 200 is performed by the system 100, including the web client 110, the communication network 120, the web server 130, and the personalization server 140.

15 Although described serially and in a particular sequence, in a preferred embodiment the steps described herein can be performed concurrently or in parallel by the system elements in response to more than one web client 110 or more than one web site 130, could be performed in a different sequence, or some combination thereof.

20 At a flow point 210, a first user at the web client 110 is ready to register with the personalization server 140.

 At a step 211, the web client software 111 sends a message 151 to the
25 personalization server 140. The message 151 includes a request to register the first user.

 At a step 212, the personalization server 140 generates and sends a registration page 153 to the web client 110. The registration page 153 can be a standard form, or can be personalized in response to the user or in response to the web client 110.

30 At a step 213, the user supplies authentication and personalization information to the web client software 111, in response to the registration page 153.

At a step 214, the web client software 111 sends the authentication and personalization information for the user to the personalization server 140.

At a step 215, the personalization server 140 records the authentication and personalization information for the user in its database 144.

At a flow point 220, a first user at the web client 110 is ready to register a new web site 130 with the personalization server 140.

At a step 221, the web client software 111 sends a message 151 to the personalization server 140. The message 151 includes a request to register the new web site 130, and information about the web site 130 useful for registration, such as an identifier 152 for a registration page 153 at the web site 130.

At a step 222, the personalization server 140 generates and sends a message 151 to request to register the first user with the web site 130. In a preferred embodiment, the message 151 requests the registration page 153 from the web site 130.

At a step 223, the web site 130 generates and sends a registration page 153 to the personalization server 140. The nature of this activity by the web site 130 can vary widely and still be within the scope and spirit of the invention.

At a step 224, the personalization server 140 responds to the web site 130. The personalization server 140 matches the registration request from web site 130 with profile information contained in the database 144 and supplies the authentication and personalization information for the user to the web site 130. In a preferred embodiment the personalization server 140 requires verification from the user by sending the web client 110 a corresponding message 151 (such as an HTML or XML page). In a preferred embodiment, the personalization server 140 generates a new email address for the user at the personalization server 140; this new email address is specific to both the user and to the web site 130.

At a step 225, the web site 130 records the authentication and personalization information for the user in its database 134.

Some web sites 130 send an initial email message 151 to the user with further authentication information, such as a username and password. The personalization server 140 receives this initial email message 151, parses it, and if it includes further authentication
5 information (such as a username and password), records that information in its database 144 for the user.

Some web sites 130 send a cookie or other data to the user with further authentication information. The personalization server 140 assures that the data (includeing
10 whatever information is associated with the "cookie") is recorded at the personalization server 140..

In a preferred embodiment, the personalization server 140 determines if the web site 130 sends a cookie to the web client 110. If so, the personalization server 140 sends
15 a software assistant 115 to the web client 110 for the web client 110 to use when using the web site 130. The software assistant 115 assists the web client software 111 and the personalization server 140 by assuring that information in the cookie is available to the personalization server 140.

20 In a preferred embodiment, the software assistant 115 includes a web browser plug-in, or a program fragment (such as an applet or JavaScript code), or some other application that operates in conjunction with the web client software 111.

At a flow point 230, a first user at the web client 110 is ready to identify and
25 authenticate themselves with a web site 130, using the personalization server 140.

At a step 231, the web client software 111 sends a message 151 to the personalization server 140. The message 151 includes a request to identify and authenticate the user with a web site 130.

30

At a step 232, the personalization server 140 generates a registration page 153. The registration page 153 identifies those web sites 130 for which the user is registered (or

has bookmarks), and allows the user to select one or more at which to identify and authenticate themselves.

At a step 233, the user selects one or more web sites 130 at which to identify
5 and authenticate themselves. The web client software 111 sends a message 151 to the personalization server 140 indicating those web sites 130.

At a step 234, the personalization server 140 sends an authentication message to the web site 130. The personalization server 140, either directly or indirectly (using the
10 web client 110), supplies the authentication and personalization information for the user to the web site 130.

At a step 235, the web site 130 authenticates the user and allows the web client software 111 access to otherwise restricted information or services.
15

At a flow point 240, a first user at the web client 110 is ready to access email directed to the first user at the personalization server 140.

At a step 241, the web client software 111 sends a message 151 to the
20 personalization server 140. The message 151 includes a request to access email at the personalization server 140.

At a step 242, the personalization server 140 generates and sends a message 151 in response to the web client 110. In a preferred embodiment, the message 151 indicates
25 for which email addresses any email has been received, and can further summarize that email (such as by presenting headers or subject lines).

At a step 243, the user accesses email at the personalization server 140 using known web-based email methods. In addition to known web-based email methods, the user
30 can direct the personalization server 140 to eliminate email addresses for one or more selected web sites 130, or to forward email for one or more selected web sites 130 to a selected target email address (possibly at another location).

At a flow point 250, a first user at the web client 110 is ready to allow access by a second user to one or more selected web sites 130.

At a step 251, the web client software 111 sends a message 151 to the
5 personalization server 140. The message 151 includes a request to allow access by a second user to one or more selected web sites 130.

At a step 252, the personalization server 140 generates a selection page 153 and sends that page 153 to the web client 110. The selection page 153 indicates a set of web
10 sites 130 for which the first user has access and indicates a set of types of restrictions on that access the first user can order the personalization server 140 to implement.

At a step 253, the web client software 111 presents the selection page 153 to the user. The user selects one or more web sites 130, as well as associated restrictions on
15 information or services at those web sites 130, and identifies a set of second users to be allowed restricted access.

At a step 254, the web client software 111 sends a message 151 to the personalization server 140 with the selections made by the first user. The personalization
20 server 140 receives the message 151 and records associated information in its database 144.

At a flow point 260, a second user at the web client 110 is ready to access one or more selected web sites 130 using the personalization server 140.

At a step 261, similar to the step 231, the web client software 111 sends a
25 message 151 to the personalization server 140. The message 151 includes a request to identify and authenticate the second user with a web site 130.

At a step 262, the personalization server 140 determines, in response to its
30 database 144, the degree of access allowed to the second user. For example, the second user can have been authorized by (one or another) first user to have access, or the second user can have independent access to the web site 130 in response to a separate registration with the personalization server 140.

In response to the degree of allowed access, similar to the step 232, the personalization server 140 generates a registration page 153. The registration page 153 identifies those web sites 130 for which the second user is allowed access, by (one or another) first user or independently, and allows the second user to select one or more at which to access (either for identification and authentication, or for bookmarks, to directly access).

At a step 233, the second user selects one or more web sites 130 at which to identify and authenticate themselves. The web client software 111 sends a message 151 to the personalization server 140 indicating those web sites 130.

At a step 234, the personalization server 140 supplies the authentication and personalization information for the first user to the web site 130 (even though the second user is the one to actually use the web site 130), either directly to the web site 130, or using the web client software 111. The choice of whether authenticate and personalize the second user directly or indirectly can be responsive to a parameter selected by the first user.

At a step 235, the web site 130 authenticates the second user (in response to the first user's authentication and personalization information) and allows the web client software 111 for the second user access to otherwise restricted information or services.

II.

System Elements

Figure 3 shows a block diagram of a system for group access to web sites.

A system 100 includes a set of web clients 110, a communication network 120, at least one web site 130, and a group surfing server 140.

As used herein, the terms "client" and "server" refer to client-server relationships between client and server, not necessarily to particular physical devices.

As used herein, the phrase "web client" includes any combination of devices or software taking on the role of a client in a client-server environment in the internet, the world wide web, or an equivalent or extension thereof. There is no particular requirement that the web clients 110 must be individual devices. They can each be a single device, a set of
5 cooperating devices, a portion of a device, or some combination thereof (such as for example a device providing web server services that acts as an agent of the user).

As used herein, the phrase "web site" includes any combination of devices or software taking on the role of a server in a client-server environment in the internet, the world
10 wide web, or an equivalent or extension thereof. There is no particular requirement that the web sites 130 must be individual devices. They can each be a single device, a set of cooperating devices, a portion of a device, or some combination thereof.

The web clients 110 each include a processor operating under control of web
15 client software 111, such as a web browser, and disposed for use by an operator or user 112. In a preferred embodiment, the web client software 111 includes software disposed for communicating with the web site(s) 130 using a communication protocol, as described below.

In a preferred embodiment, the web clients 110 each include a general-purpose
20 computer, such as a laptop or workstation. However, the web clients 110 can also include (either alone or in conjunction with a laptop or workstation), a hand-held calendar (such as a "Palm Pilot" or other hand-held device), a portable computer, a special purpose computer, a cellular telephone or other telephonic device, a web server acting as the agent for a user, or another device. In alternative embodiments, the web clients 110 may also include any other
25 device disposed for performing the all or some functions described herein. The location, the type of device, and the nature of the connection of the web clients 110 to the web site 130 can each differ between pairs of connection sessions between the web clients 110 and the web site 130.

30 In a preferred embodiment, the communication network 120 includes a packet switched network such as the Internet, as well as (in conjunction with or instead of) an intranet, an enterprise network, an extranet, a virtual private network, a virtual switched network. In alternative embodiments, the communication network 120 may include any other

set of communication links that couple the web clients 110, web site 130, and group-surfing server 140 so they can perform the functions described herein.

The communication network 120 is disposed for transporting messages 151
5 between any two of the web clients 110, the web site 130, and the group-surfing server 140. The messages 151 are formatted in the communication protocol recognized by the web clients 110, the web site 130, and the group-surfing server 140. In a preferred embodiment, the communication protocol includes TCP/IP (transfer control protocol/ Internet protocol), or HTTP (hypertext transfer protocol) a variant thereof, such as HTTPS (secure HTTP). In a
10 preferred embodiment, the communication protocol can include an additional protocol operating over TCP/IP. The communication protocol can also include other protocols for requesting and sending information, including FTP (file transfer protocol), Gopher, and variants thereof. Although the description refers herein primarily to HTTP and TCP/IP, those of ordinary skill in the art will recognize, after perusing this application, that use of the
15 invention with other protocols would not require new invention or undue experimentation.

In a preferred embodiment, those messages 151 that request information can include an identifier 152 for a requested page 153. The page 153 includes a set of information, possibly including data in one of a number of formats, and possibly also includes
20 a set number of links 154 to other pages 153. Each link 154 includes an identifier 152 for its target page 153, and information about the target page 153 (such as a title).

In a preferred embodiment, each page 153 can include data in the form of text, images (still or animated), sound, program fragments (such as applets, applications, or
25 JavaScript), or combinations thereof.

In a preferred embodiment, the web site 130 includes a processor operating under control of web server software 131, and disposed for delivering information 132 to the web clients 110 or the group-surfing server 140 in response to requests made using the
30 communication protocol. In a preferred embodiment, the web site 130 includes software disposed for communicating with the web clients 110 or the group-surfing server 140 using the communication protocol.

Creating a Group-Surfing Session

The web client software 111 is disposed for sending a message 151 to the group-surfing server 140, to request the group-surfing server 140 to respond and perform functions described herein. In a preferred embodiment, the message 151 is responsive to an action by the user of the web client software 111, such as by selecting a web page or a link to a web page.

A first web client 110 sends a session-creation message 151 to the group-surfing server 140, to request the group-surfing server 140 to create or set up a group-surfing session. In a preferred embodiment, the message 151 includes an identifier for the group-surfing session, so that other web clients 110 can add themselves to that session. (The group-surfing server 140 can also assign this identifier in a reply to the session-creation message 151.) In a preferred embodiment, the message 151 includes identifiers for a set of web clients 110 participating in, permitted to participate in, or forbidden from participating in, that session. The web client 110 can alternatively specify that the session is open to anyone. The web client 110 can also specify a time schedule for the session (these functions can be combined, so that for example, the session can be open to anyone for a selected time period, after which only certain authorized users may participate).

In a preferred embodiment, the message 151 can also include an identifier 152 for an initial page 153 for the group-surfing session. For example, the initial page 153 can include a home page for a selected web site 130 or a welcome page for a selected service available at the selected web site 130.

The group-surfing server 140 receives the session-creation message 151, and responds by (1) creating a group-surfing session, and (2) informing the participants in the group-surfing session. When the session-creation message 151 includes an identifier 152 for an initial page 153, the group-surfing server 140 proceeds to begin operation of the group-surfing session, as described below, causing the web site 130 to deliver the initial page 153 to the web clients 110 participating in the session.

After creating the group-surfing session, the group-surfing server 140 prepares to add additional web clients 110 to the session. To add itself to the session, a second (or further) web client 110 sends a session-join message 151 to the group-surfing server 140. In a preferred embodiment, the message 151 includes the identifier for the group-surfing session.

5

The group-surfing server 140 receives the session-join message 151, and responds by adding the new web client 110 to the group-surfing session. The group-surfing server 140 can also inform the other participants in the group-surfing session of the newly added web client 110. The group-surfing server 140 causes the newly added web client 110 to participate in the session, as described below.

10

Operating the Group-Surfing Session

One or more of the web clients 110 are designated by the group-surfing server 140 as a controlling web client 110, and are therefore empowered by the group-surfing server 140 to control the group surfing session. The choice of which web clients 110 are designated as the controlling web clients 110 can be made in any one of, or some combination of, a variety of techniques:

20 o The controlling web clients 110 are identified in the session-creation message 151.

o The controlling web client 110 is, or the controlling web clients 110 are selected by (either once at the beginning of the session or dynamically at times throughout the session), the web client 110 that contacted the group-surfing server 140 to create the session.

25

o The controlling web clients 110 are designated using a random or pseudo-random technique by the group-surfing server 140 from those web clients 110 participating in the session.

30 o The controlling web clients 110 are designated by a majority or plurality vote of all web clients 110 participating in the session.

o The controlling web clients 110 are the first M of the first N web clients 110 participating in the session that attempt to select a next page. The selection of which M out of N web clients 110 can be made by the group-surfing server 140 using a random or pseudo-random technique, a clustering technique for selecting web clients 110 that are similar, or
5 another technique.

o The controlling web clients 110 are selected by the group-surfing server 140 to be all those web clients 110 participating in the session that meet selected criteria. The selected criteria can be rule-based, such as for example (a) those web clients 110 having ".edu" as their
10 primary domain or ".aol" as their secondary domain, (b) those web clients 110 having participated in the session for more than N seconds, (c) those web clients 110 having participated in the session but not yet having been selected as the controlling web client 110, or some combination thereof.

15 If the controlling web client 110 is a single web client 110, that single controlling web client 110 determines the progression of pages 153 viewed during the group-surfing session, as described below.

If there is more than one controlling web client 110, those controlling web
20 clients 110 act in concert to determine the progression of pages 153 viewed during the group-surfing session. The group-surfing server 140 can determine the progression of pages 153 in any one of, or some combination of, a variety of techniques:

o The first page 153 selected by any controlling web client 110 is selected as the next
25 one in the progression of pages 153 in the session.

o The next one in the progression of pages 153 in the session is designated using a random or pseudo-random technique by the group-surfing server 140 from those pages 153 selected by any of the controlling web clients 110.

30 o The next one in the progression of pages 153 in the session is designated using a round-robin technique by the group-surfing server 140 from those pages 153 selected by any of the controlling web clients 110.

o The page 153 selected by a majority or a plurality of controlling web clients 110 is selected as the next one in the progression of pages 153 in the session.

5 In any event, the group-surfing server 140 determines a next one in the progression of pages 153 in the session. The group-surfing server 140 contacts the web site 130 having that next page 153, and directs that target web site 130 to deliver that next page 153 so it can be presented to those web clients 110 participating in the session.

10 In a preferred embodiment, the group-surfing server 140 directs the target web site 130 to deliver that next page 153 to the group-surfing server 140 itself. The group-surfing server 140 then re-sends that page 153 to those web clients 110 participating in the session. This allows usage of a single set of "cookies," or other data related to identity or session, sent by the web site 130 and stored by the group-surfing server 140 at each participating web
15 client 110.

In alternative embodiments, where no "cookies" or other data related to identity are involved, each web client 110 can receive the next page 153 directly from the web site 130. In some such alternative embodiments, the group-surfing server 140 may retrieve
20 that next page 153 itself from the target web site 130, and re-send that next page 153 to each web client 110 participating in the session. In other such alternative embodiments, the group-surfing server 140 may use a multicast protocol such as the IGMP protocol (Internet Group Management Protocol), to multicast the next page 153 to those web clients 110 participating in the session.

25

As the controlling web client 110 selects a progression of pages 153 for the session, that progression of pages 153 is presented at each of the web clients 110 participating in the session.

30 If any web client 110 participating in the session desires to leave the session, either permanently or temporarily, that web client 110 sends a session-exit message 151 to the group-surfing server 140. The group-surfing server 140 receives the session-exit message 151, and responds by removing the exiting web client 110 from the group-surfing session.

The group-surfing server 140 can also inform the other participants in the group-surfing session of the exiting web client 110. The group-surfing server 140 causes the exiting web client 110 to no longer participate in the session.

5 The functions for the web site 130 are not substantially different from those performed by the web site 130 in response to similar requests from others, including possibly the web client software 111. Accordingly, there is no particular requirement that the web server 130 be modified to operate in conjunction with the web client software 111 and the group-surfing server 140 to perform the functions described herein.

10

 When performing group-surfing for more than one type of web client 130 (such as a first web client 130 including a personal computer and a second web client 130 including a "Palm Pilot" device), the group-surfing server 140 makes multiple requests for the web site 130 to send (variants of) the same page, so as to retrieve the most suited version of the page for each separate web client 110. The group-surfing server 140 forwards to each
15 separate web client 110 the variant of the page that is most suited to that separate web client 110.

Efficient Group-Surfing Session Activity

20

 In a preferred embodiment, load is reduced on the group-surfing server 140 using a program fragment loaded at each web client 110. The program fragment can include one or more of, or any combination of, a Java applet, a section of JavaScript code, a web browser plug-in, an active-X element, or another technique for interfacing with the web client
25 110 and affecting its operation with the web site 130 and the group-surfing server 140.

 The program fragment can be sent from the group-surfing server 140 to the web client 110, or can be resident at the web client 110. The program fragment can be loaded dynamically for the session, or can be permanently resident but only active for the session.

30

 The program fragment can perform one or more of, or some combination of, the following functions:

- o The program fragment can detect embedded frames included in selected pages 153 and request the group-surfing server 140 to retrieve those frames from the web site 130 and send them to the web client 110.
- 5 o The program fragment can intercept selection of a link 152 at the web client 110 and direct that selection to the group-surfing server 140 for processing.
- o The program fragment can intercept "submit" selections by the web client 110 during posting of HTML forms, and direct the information in those "submit" selections to the group-surfing server 140 for processing.
- 10 o The program fragment can intercept HTML instructions in selected pages 153, which instructions would interfere with the screen layout used for the session (such as HTML code that attempts to force itself into a top-level frame).
- 15 o The program fragment can detect embedded multimedia objects included in selected pages 153 and request those multimedia objects directly from the web site 130.

Variations on the Group-Surfing Session

20

There are many variations of techniques by which individual web clients 110 can access information from web sites 130. There are similarly many variations of techniques by which the controlling web client 110 can access information from web sites 130 and cause that information to be presented to those web clients 110 participating in the session. These

25 can include one or more of, or some combination of, the following:

Web Page Look Ahead

The controlling web client 110 can select web pages 153 for "look ahead"

30 before designating those web pages 153 as next pages 153 in the progression of pages 153 in the session. This allows the controlling web client 110 to provide for one or more of, or some combination of, the following contingencies:

- o The user 112 at the controlling web client 110 can determine if the selected “look ahead” pages 153 are accessible at the time of the session. For example, some such pages 153 can be subject to restricted access in response to time or usage constraints.
- 5 o The user 112 at the controlling web client 110 can determine if the selected “look ahead” pages 153 are appropriate for the web clients 110 participating in the session. For a first example, some such pages 153 can include information that is immaterial to the session (such as for a class, a seminar, or a demonstration of a product or service). For a second example, some such pages 153 can include information that is inappropriate for the session
- 10 (such as so-called “adult-oriented” material for a session including users 112 who are minors).
- o The user 112 at the controlling web client 110 can determine if the selected “look ahead” pages 153 require special access (such as password restriction or cost-burdened services). For a first example, the controlling web client 110 can choose to exclude such
- 15 pages 153 from the session. For a second example, the controlling web client 110 can choose to accept such special access (such as entering a password or credit card number) without presenting that acceptance to other web clients 110 participating in the session.

Web Page Special Access

20

- The controlling web client 110 can select web pages 153 for special access when designating those web pages 153 as next pages 153 in the progression of pages 153 in the session. For a first example, the controlling web client 110 can enter information required for special access privately, without presenting that information to other web clients 110
- 25 participating in the session. For a second example, the controlling web client 110 can enter such information (such as for completing an HTML “form”) using information available from, and supplied by, other web clients 110 participating in the session.

Web Page Automatic Form Completion

30

In a preferred embodiment, the controlling web client 110 enters information to complete the HTML form, and sends that information to the group-surfing server 140. The group-surfing server 140 enters information to complete the HTML form, and sends that

information to the web site 130. When the web site 130 replies with a new page, the group-surfing server 140 sends that new page to all participating web clients 130.

5 In alternative embodiments, the when the controlling web client 110 enters information to complete the HTML form, and sends that information to the group-surfing server 140, the group-surfing server 140 may present that information on the HTML form at each participating web client 110, so that each participating web client 110 can see the HTML form being filled in. The group-surfing server 140 may present that information on the HTML form as each field of the form is completed, or when the entire form is completed, or
10 at other times.

Payment for Web Site Services

The controlling web client 110 can select web pages 153 for paid access, even
15 if the web clients 110 participating in the session do not have the right to such paid access. The group-surfing server 140 can control paid access in one or more of, or some combination of, the following techniques:

- o The controlling web client 110 can pay for that access itself, effectively presenting a
20 gift of services to participating web clients 110.
- o The group-surfing server 140 can exact a payment from accounts of those participating web clients 110. This payment can be a pro-rata share of the actual cost to the controlling web client 110, can be a pre-selected amount agreed by the participating web
25 clients 110, or can be a commission paid to the group-surfing server 140 by the transacting web site 130.
- o The group-surfing server 140 can exact such payment only from those participating web clients 110 that choose to have the paid information or services presented to them as part
30 of the session. The participating web clients 110 can make this decision either at the time they join the session or at the time the payment for information or services is (about to be) incurred.

Affiliated Electronic Commerce

The controlling web client 110 can select web pages 153 for participation in electronic commerce. For example, the controlling web client 110 can order goods or services for delivery. Similar to payment for web site services, the web clients 110 participating in the session need not be required to participate in this electronic commerce. The group-surfing server 140 can control such electronic commerce in one or more of, or some combination of, the following techniques:

- 10 o The controlling web client 110 can pay for the ordered goods or services itself, effectively presenting gifts to participating web clients 110.
- o The group-surfing server 140 can exact payment from accounts of those participating web clients 110 for a single instance of such electronic commerce. This payment can be a
15 pro-rata share of the actual cost to the controlling web client 110, can be a pre-selected amount agreed by the participating web clients 110, or can be a commission paid to the group-surfing server 140 by the transacting web site 130.
- o The group-surfing server 140 can exact such payment only from those participating
20 web clients 110 that choose to have the paid information or services presented to them as part of the session. Similarly to paid web site services, the participating web clients 110 can make this decision either at the time they join the session or at the time the payment for information or services is (about to be) incurred.
- 25 o The group-surfing server 140 can duplicate the electronic commerce transaction for each participating web client 110 that chooses to participate. Similarly to paid web site services, the participating web clients 110 can make this decision either at the time they join the session or at the time the payment for information or services is (about to be) incurred.
- 30 and
- o The group-surfing server 140 can receive a pre-payment prior to the group-surfing session, so that an associated web client participating that chooses to participate in the group-surfing session can use that payment for electronic commerce. Thus, the group-surfing server

140 can allow payments from a pre-paid (or otherwise arranged) "account" on behalf of one or more of, or a class of, web clients 110.

5 This function can be useful for making joint decisions regarding electronic commerce, such as for selecting gifts for third parties or for one of the session participants.

Import and Export of Web Site Information

10 The controlling web client 110 can import or export information related to web sites 130, including bookmarks, "cookies," and user registrations at participating web sites 130. Similarly to paid web site services, web clients 110 participating in the session can choose whether or not to participate in these import or export operations.

Use in Conjunction with Intra-User Communication

15 Those web clients 110 participating in the session can also communicate between and among groups of users 112 at those web clients 110. The techniques used for communication can include one or more of, or some combination of, the following: telephone communication, voice over IP, Internet chat, electronic mail, "instant messaging," or other
20 intra-user communication. In a preferred embodiment, the communication technique can be presented to each web client 110 at the initiation of the group-surfing server 140, using either a same or a separate window at the web client 110.

Use in Conjunction with Other Network Functions

25 Those web clients 110 participating in the session can also perform other functions associated with the network. For example, the use of the invention in conjunction with electronic commerce is described above.

30 The invention can also be used for remote training functions. In such uses, one or more of the participating web clients 110 would be instructors, teachers, seminar presenters, discussion facilitators, or other types of moderator. These participating web clients 110 can be controlling web clients 110. Additional participating web clients 110 (who

could substantially outnumber the moderators) would be students, seminar participants or reviewers, discussion participants, or negotiating parties. The instructors or moderators can use the group-surfing process to present information to the students or participants, to confirm assumptions or assertions using available reference services or reference works, and the like.

5

The invention can also be used for virtual displays or tours. In such uses, one or more of the participating web clients 110 would be salespeople, docents, presenters, or other types of guide. These participating web clients 110 can be controlling web clients 110. Additional participating web clients 110 (who could substantially outnumber the moderators or could be interacting one-to-one with the salesperson or guide) would be potential customers or virtual tourists. The salespeople or guides can use the group-surfing process to present information to the potential customers or virtual tourists in response to perceived desires or tastes of the potential customers or virtual tourists, using available reference material, including maps, pictures, and other visual data. In a preferred embodiment of such uses, the available reference material includes a VRML (virtual reality markup language) server, at which three-dimensionally viewable information about the topic of the presentation or tour is available. For example, the three-dimensionally viewable information can include presentations of real estate for sale, or a virtual art gallery.

20

The invention can also be used for telemedicine or other process telecontrol. In such uses, one or more of the participating web clients 110 would be controlling surgeons, physicians, other medical personnel, or other consultants. These participating web clients 110 can be controlling web clients 110. Additional participating web clients 110 would be on-site medical personnel, on-site engineering personnel, or robotic devices. The controlling medical personnel can use the group-surfing process to review information about a patient (or a controllable physical process, such as an oil refinery or a semiconductor manufacturing facility), to make suggestions or issue orders regarding treatment, and to directly control robotic devices or sensor apparatus.

30

The invention can also be used for consulting (such as in the fields of finance, advertising or marketing). In such uses, one or more of the participating web clients 110 would be consultants. These participating web clients 110 can be controlling web clients 110. Additional participating web clients 110 would be the consultants' (human) client or clients,

such as marketing personnel. The consultant can use the group-surfing process to present information to the client, including new or proposed presentation material, or presentation material from competitors or other participants in the electronic marketplace.

5 Multiple Group-Surfing "Channels"

 The group-surfing server 140 can maintain more than one separate group-surfing session, with each separate group-surfing session having its own history of viewed pages. When a web client 110 adds itself to the participating web clients 110 in a group-surfing session, it is presented with the most recent viewed page, and is able to review the
10 history of pages viewed prior to joining that group-surfing session.

 In a preferred embodiment, when an individual user of a web client 110 using ordinary web surfing techniques comes upon a page that the user desires to share, that user
15 can, using its web client 110, send a message to the group-surfing server 140 to add that page to a group-surfing session. Each such web client 110 can have its own personalized group-surfing session, which a second web client 110 can view and view the history thereof. If the second web client 110 is already participating in that group-surfing session, the page would be presented to the second web client 110 when it is sent by the first web client 110 to the group-surfing server 140. In alternative embodiments, the second web client 110 can receive only a
20 list of pointers (such as URLs) to those pages presented during the group-surfing session, dynamically updated when a new page is added.

System Operation

25

 Figure 4 shows a process flow diagram for a method of using a system for group access to web sites.

 A method 200 is performed by the system 100, including the web client 110,
30 the communication network 120, the web server 130, and the group-surfing server 140.

Although described serially and in a particular sequence, in a preferred embodiment the steps described herein can be performed concurrently or in parallel by the system elements, could be performed in a different sequence or some combination thereof.

5 At a flow point 210, the group-surfing server 140 is ready to create a group-surfing session.

 At a step 211, a first web client 110 sends a session-creation message 151 to the group-surfing server 140, as described above, to request the group-surfing server 140 to
10 create or set up a group-surfing session.

 At a step 212, the group-surfing server 140 receives the session-creation message 151. The group-surfing server 140 (1) creates the group-surfing session, and (2) informs the participants in the group-surfing session.
15

 The method 200 continues at the flow point 220.

 At a flow point 220, the group-surfing server 140 is ready to add web clients 110 to a group-surfing session.
20

 At a step 221, a second (or further) web client 110 sends a session-join message 151 to the group-surfing server 140, as described above.

 At a step 222, the group-surfing server 140 receives the session-join message
25 151. The group-surfing server 140 (1) adds the new web client 110 to the group-surfing session, and (2) inform the other participants in the group-surfing session of the newly added web client 110.

 At a step 223, the group-surfing server 140 sends to the new web client 110 a
30 program fragment (preferably a Java applet and JavaScript code) that processes those pages 153 received as part of the session. When the new web client 110 selects a link 152 on one such page 153, the program fragment intercepts the request before it is sent to the web site 130, and redirects the selection to the group-surfing server 140. The group-surfing server 140

is thus able to determine which next pages 153 are selected, and to assure that such next pages 153 are presented to all participating web clients 110.

The method 200 continues at the flow point 230.

5

At a flow point 230, the group-surfing server 140 is ready to perform a group-surfing session.

At a step 231, the group-surfing server 140 designates one or more controlling web clients 110, as described above. In a preferred embodiment, the first web client 110, which sent the session-creation message 151, is the single controlling web client 110.

At a step 232, the controlling web client 110 receives a page 153 from the group-surfing server 140, which received that page 153 from the web site 130. When the controlling web client 110 selects a link 152 on the page 153, the selection is caught by the program fragment, which sends the selection to the group-surfing server 140 as described below (preferably using a protocol operating on top of TCP/IP). In alternative embodiments, the group-surfing server 140 may modify the links 152 in the page 153 before presenting that page 153 to web clients 110 participating in the session.

20

At a step 233, the controlling web client 110 sends a next-page message 151 to the group-surfing server 140, indicating the next page 153 in the progression of pages 153 in the session.

25

At a step 234, the group-surfing server 140 receives the next-page message 151. The group-surfing server 140 (1) contacts the web site 130 having that next page 153 after adding proper cookie or other identity information, and directs that target web site 130 to deliver that next page 153 to the group-surfing server 140 itself. The group-surfing server 140 then re-sends that page 153 to those web clients 110 participating in the session.

30

In a preferred embodiment, in order to reduce load on the group-serving server 140, the group-serving server 140 sends only the page 153 itself without any multimedia

elements (such as embedded sound, images, or program fragments). Each participating web client 110 requests those multimedia elements directly from the web site 130.

At a step 235, the page 153 is presented at each of the web clients 110
5 participating in the session.

At a step 236, if the group-surfing server 140 receives a "cookie" or other data relating to identity or session from the web site 130, the group-surfing server 140 records the "cookie" in a cookie database relatively local to the group-surfing server 140 and session.
10 Each time the group-surfing server 140 requests a page from the web site 130, the group-surfing server 140 also sends any relevant "cookies" that were received from the web site 130.

The step 231, the step 232, the step 233, the step 234, the step 235, and the step 236 are performed repeatedly so that the progression of pages is presented at each of the web
15 clients 110 participating in the session.

At a flow point 240, a selected web client 110 is ready to leave the session.

At a step 241, the selected web client 110 sends a session-exit message 151 to
20 the group-surfing server 140.

At a step 242, the group-surfing server 140 receives the session-exit message 151. The group-surfing server 140 (1) removes the exiting web client 110 from the group-surfing session, and (2) informs the other participants in the group-surfing session of the
25 exiting web client 110.

In a preferred embodiment, if the controlling web client 110 leaves the session, the group-surfing server 140 (1) terminates the session, and (2) informs the participants in the group-surfing session.
30

At a flow point 250, the controlling web client 110 is ready to select web pages 153 for "look ahead."

At a step 251, the controlling web client 110 sends a look-ahead-start message 151 to the group-surfing server 140.

At a step 252, the group-surfing server 140 receives the look-ahead-start message 151. The group-surfing server 140 refrains from presenting following pages 153 to participants in the session.

At a step 253, the controlling web client 110 sends messages 151 to one or more web sites 130 to request pages 153 and receive information from those web sites 130, without having that information presented to participants in the session.

At a step 254, the controlling web client 110 sends a look-ahead-stop message 151 to the group-surfing server 140.

At a step 255, the group-surfing server 140 receives the look-ahead-stop message 151. The group-surfing server 140 returns to presenting following pages 153 to participants in the session.

At a flow point 260, the controlling web client 110 is ready to select web pages 153 for "special access."

At a step 261, the controlling web client 110 sends a special-access-start message 151 to the group-surfing server 140.

At a step 262, the group-surfing server 140 receives the special-access-start message 151. The group-surfing server 140 refrains from presenting access or authentication information (such as HTML forms) to participants in the session.

At a step 263, the controlling web client 110 sends messages 151 to one or more web sites 130 to obtain access to those web sites 130, without having that information presented to participants in the session.

At a step 264, the controlling web client 110 sends a special-access-stop message 151 to the group-surfing server 140.

At a step 265, the group-surfing server 140 receives the special-access-stop message 151. The group-surfing server 140 returns to regular presentation of information in pages 153 to participants in the session.

At a flow point 270, the controlling web client 110 is ready to select web pages 153 for paid access.

10

In a preferred embodiment, the group-surfing server 140 does not exact any payment from the web clients 110 participating in the session. Accordingly, all paid access is paid for by the controlling web client 110, and is effectively given away free to those web clients 110 participating in the session. The group-surfing server 140 takes no special action.

15

At a flow point 280, the controlling web client 110 is ready to select web pages 153 for participation in electronic commerce.

In a preferred embodiment, the group-surfing server 140 does not exact any payment for participation in electronic commerce. Accordingly, all electronic commerce is paid for by the controlling web client 110, and (if a service) is effectively given away free to those web clients 110 participating in the session. The group-surfing server 140 takes no special action.

20

In alternative embodiments, the group-surfing server 140 may be registered as a partner or affiliate of the web site 130, and thus receives a commission from the web site 130 for electronic commerce conducted during the session.

At a flow point 290, the controlling web client 110 is ready to import or export information related to web sites 130.

30

At a step 291, the controlling web client 110 sends an import-export message 151 to the group-surfing server 140, directing import or export of information relating to web sites (such as bookmarks, "cookies," or user registrations at participating web sites 130)

5 At a step 292, the group-surfing server 140 receives the import-export message 151. The group-surfing server 140 imports or exports the designated information to selected databases at web clients 110 participating in the session that indicate their willingness to participate in the import or export operation.

10 In a preferred embodiment, the selected databases are specific to a cookie/identity database for the group-surfing session. In alternative embodiments, the selected databases may also be available to other applications for web use, such as bookmark and registration databases for generic web surfing. The selected databases can be managed by the program fragment sent to the web client 110 from the group-surfing server 140, or by
15 other related software.

III.

Lexicography

20 As used herein, use of the following terms refer or relate to aspects of the invention as described below.

- **personalized information** – As used herein, the phrase "personalized information" includes any data collected by, from or about a user or a web site that can be stored on a
25 personal data server.

Personalized information can include one or more of the following: financial information (such as bank account balances, credit information, loan information, real estate information, stock account balances, stock portfolio information, or other financial
30 information); medical information (such as allergy information, insurance information, medication information, patient history information, or other medical information; or other information specific to an individual or not generally available to the public.

Personalized information can also include information of personal interest to an individual user, even if that information is not specific to an individual and still generally available to the public, but of specific interest to the individual, such as personalized news or other generic information asked for by the individual user in a specific way. This can include

5 (1) information about selection of the individual user's child in a classroom or sports team in a league; (2) news items of interest to the individual user; (3) bids at auction sites made by or otherwise of interest to the individual user; (4) web-email or other communications such as chat, instant messaging, or newsgroups, made by or to or otherwise of interest to the individual user; (5) last or pending transactions with a stockbroker or other broker or a

10 book vendor or other vendor; (6) records of non-monetary accounts, such as frequent flier miles or other discount programs; (7) sports information, such as golf scores or a record for selected sports teams; or (8) calendar information, such as a status of meeting invitations or a personal calendar.

15 Personalized information can also include information also information the individual user would use to act with, such as for performing e-commerce. For example, personalized information can include information to automate purchases, such as the individual user's name and address, credit card number, account number, delivery address and profile of delivery preferences, or the individual users' preferred account for purchases.

- 20
- **summarization and aggregation** – As used herein, the phrase “summarization and aggregation” includes all techniques and methodologies for the organization, selective or nonselective segregation, linking, selective presentation and selective transfer of personalized information.

25 Summarization or aggregation can include one or more of the following: adding or totaling account balances or account values, adding or totaling securities holdings from individual accounts, computing or determining a blend of multiple sources of credit information or other financial information, or other forms of summarization or

30 aggregation that present a more global picture from more specific information. For multiple individuals, summarization or aggregation can include those forms of demographic or population grouping used in census, insurance, or market research applications.

Summarization or aggregation can include a default set of information to summarize or to aggregate, a selection by an individual user of preferences or what specific information to summarize or to aggregate, or a request by an individual user to summarize or aggregate using an editor or other tool.

- **personal data server** – As used herein, the phrase “personal data server” includes a server device which has access to web sites that include personalized information, as described above, and can include access information or preferences of an individual user for retrieving or using that personalized information. The personal data server can also have access to web sites with information of personal interest to the individual user, even when that information is not specific to that particular individual user.
- **individual user** – As used herein, the phrase “individual user” includes any person who acts either on behalf of themselves or an entity and manipulates a web client in such a way as to gain access to the Internet and who manipulates that web client so as to use, add to, aggregate, summarize, delete, or access data contained on a personal data server that is unique to them or the entity they represent.
- **web site** – As used herein, the phrase “web site” includes any combination of devices or software taking on the role of a server in a client-server environment in the Internet, the world wide web, or an equivalent or extension thereof. There is no particular requirement that the web sites must be individual devices. They can each be a single device, a set of cooperating devices, a portion of a device, or some combination thereof.
- **jump page** – As used herein, the phrase “jump page” refers to a web page used by the personal data server to present personalized data that the individual user can peruse. The “jump page” can also be used to navigate directly to one or more web sites having that information at hand.
- **navigate** - As used herein, the phrase “navigate” includes activities whereby by a an individual user uses a web client to access information and move from one web site to

another web site, one web page to another web page, within a web page, and onto and off of an internet, intranet or other network.

- 5 • **e-commerce or electronic commerce** – As used herein, the phrase “ecommerce” or “electronic commerce” includes all commercial, business, professional and investment activities conducted over the Internet, an intranet or any type of network.
- 10 • **inter-user communication and interest groups** – As used herein, the phrase “inter-user communication” and “interest groups” refers to any communication among users of a network or to any communication between user of a network and a USENET, or computer bulletin board, or newsgroup or the group involved in the aggregation and transfer of information.
- 15 • **limited access or aggregate access** – As used herein, the phrase “limited access” or aggregate access” refers the how much of an individual user’s personal data is made available to persons or entities other than the user. These limits can be set by the individual or by a pre-selected protocol. For example, an individual user may make the entirety of his medical records available to any medical professional. Alternately, the individual user may make only small portion of those records available to their personal
20 physician.
- 25 • **persons or entities other than the individual** – As used herein, the phrase “persons or entities other than the individual” includes all persons or entities other than the individual user. For instance, it may include a government agency, an insurer or other third party authorized to access personalized information, or a web site or other network link that
30 attempts to retrieve information concerning an individual user.
- **meta-bookmark** – As used herein, the phrase “meta-bookmark” includes data structures and techniques for accessing a web object, including information relating to a location of that web object and information relating to access control, or authorization or
30 identification of an entity seeking to access that web object.

For example, a meta-bookmark can include one or more of the following: (1) a link or pointer to a web object ordinarily requiring a cookie or password for access, (2) a link or pointer to a partially completed form, where some of the form fields, such as a login name or a password, have restricted presentation, or (3) a link or pointer to an application or applet that compiles aggregate information from personalized information.

A meta-bookmark can include a bookmark such as "buy this stock," which includes a link or pointer to a selected web site with a specific action, such as to login to a selected stockbroker, to select a stock for purchase, and to order purchase of that stock in a selected amount.

System Elements

Figure 5 shows a block diagram of a system for summarization and aggregation of personalized information.

A system 100 includes a set of web clients 110, a communication network 120, at least one web site 130, and a personal data server 140.

As used herein, the terms "**client**" and "**server**" refer to relationships between the client and the server, not necessarily to particular physical devices.

As used herein, the phrase "**web client**" includes any combination of devices or software taking on the role of a client in a client-server environment in the Internet, the World Wide Web, or an equivalent or extension thereof. There is no particular requirement that the web clients 110 must be individual devices. They can each be a single device, a set of cooperating devices, a portion of a device, or some combination thereof (such as for example a device providing web server services that acts as an agent of the user).

As used herein, the phrase "**web site**" includes any combination of devices or software taking on the role of a server in a client-server environment in the Internet, the world wide web, or an equivalent or extension thereof. There is no particular requirement that the

web sites 130 must be individual devices. They can each be a single device, a set of cooperating devices, a portion of a device, or some combination thereof.

As used herein, the phrase “**client device**” includes any device taking on the role of a client in a client-server relationship (such as an HTTP web client and web server). There is no particular requirement that any client devices must be individual physical devices; they can each be a single device, a set of cooperating devices, a portion of a device, or some combination thereof.

As used herein, the phrase “**server device**” includes any device taking on the role of a server in a client-server relationship. There is no particular requirement that server devices must be individual physical devices; they can each be a single device, a set of cooperating devices, a portion of a device, or some combination thereof.

The web clients 110 each include a processor operating under control of web client software 111, such as a web browser, and disposed for use by an operator or user 112. In a preferred embodiment, the web client software 111 includes software disposed for communicating with the web site(s) 130 using a communication protocol, as described below.

In a preferred embodiment, the web clients 110 each include a general-purpose computer, such as a laptop or workstation. However, the web clients 110 can also include (either alone or in conjunction with a laptop or workstation), a hand-held calendar (such as a “Palm Pilot” or other hand-held device), a portable computer, a special purpose computer, a cellular telephone or other telephonic device, a web server acting as the agent for a user, or another device. In alternative embodiments, the web clients 110 may also include any other device disposed for performing the all or some functions described herein. The location, the type of device, and the nature of the connection of the web clients 110 to the web sites 130 can each differ between pairs of connection sessions between the web clients 110 and the web sites 130.

In a preferred embodiment, the communication network 120 includes a packet switched network such as the Internet, as well as (in conjunction with or instead of) an intranet, an enterprise network, an extranet, a virtual private network, a virtual switched

network. In alternative embodiments, the communication network 120 may include any other set of communication links that couple the web clients 110, web site 130, and personal data server 140 so they can perform the functions described herein.

5 The communication network 120 is disposed for transporting messages 151 between any two of the web clients 110, the web site 130, and the personal data server 140. The messages 151 are formatted in the communication protocol recognized by the web clients 110, the web site 130, and the personal data server 140. In a preferred embodiment, the communication protocol includes TCP/IP (transfer control protocol/ Internet protocol), or
10 HTTP (hypertext transfer protocol) a variant thereof, such as HTTPS (secure HTTP). In a preferred embodiment, the communication protocol can include an additional protocol operating over TCP/IP. The communication protocol can also include other protocols for requesting and sending information, including FTP (file transfer protocol), Gopher, and variants thereof. Although the description refers herein primarily to HTTP and TCP/IP, those
15 of ordinary skill in the art will recognize, after perusing this application, that use of the invention with other protocols would not require new invention or undue experimentation.

 In a preferred embodiment, those messages 151 that request information can include an identifier 152 for a requested page 153. The page 153 includes a set of
20 information, possibly including data in one of a number of formats, and possibly also includes a set number of links 154 to other pages 153. Each link 154 includes an identifier 152 for its target page 153, and information about the target page 153 (such as a title).

 In a preferred embodiment, each page 153 can include data in the form of text, images (still or animated), sound, program fragments (such as applets, applications, or
25 JavaScript), or combinations thereof.

 In a preferred embodiment, the web site 130 includes a processor operating under control of web server software 131, and disposed for delivering information 132 to the web clients 110 or the personal data server 140 in response to requests made using the
30 communication protocol. In a preferred embodiment, the web site 130 includes software disposed for communicating with the web clients 110 or the personal data server 140 using the communication protocol.

Personal Data Server

The personal data server 140 includes a processor operating under control of both web client software 111 and web server software 141. In a preferred embodiment, the web client software 111 includes software disposed for communicating with the web site(s) 130, as described below, while the web server software 141 includes software disposed for communicating with the web client 110, as described below.

The personal data server 140 includes an access database 142 or other data structure including information regarding a set of individual users. The access database 142 includes, for each individual user, a set of web sites 130 having personalized information for that individual user, and a corresponding set of access information for each individual user for each web site 130, such as a login name and a password. In a preferred embodiment, the personal data server 140 also includes authentication information for each individual user, so that the personal data server 140 only presents personalized information to the correct individual user.

The personal data server 140 is disposed for using the access database 142, at the request of an individual user using a web client 110, for accessing those web sites 130 in the access database 142 and obtaining a set of personalized information about the individual user. The personal data server 140 includes a personalized information database 143 with this information, and dynamically generates a jump page 144 or other presentation of the personalized information for use by the individual user.

In a preferred embodiment, the jump page 144 includes at least a summary of the personalized information obtained from each web site 130, and a hyperlink or other pointer to that web site 130 for detailed review or manipulation of that personalized information by the individual user.

The hyperlink or other pointer includes an address, such as a URL (uniform resource locator) for the personalized information, and also includes access information for that personalized information. For example, the hyperlink or other pointer can include a

sequence of web navigation operations (such as links to links, links with forms with data already completed, links requiring login names and passwords, or some combination thereof).

5 The individual user can obtain the hyperlink or other pointer from the jump page, either for later use, or for distribution to another entity. The saved or transmitted hyperlink or other pointer is a meta-bookmark 145. In a preferred embodiment, the individual user can set properties for the a meta-bookmark 145, such as a limitation on data available using the meta-bookmark 145, a limitation on distribution, a password for use, an expiration date, or some combination thereof.

10

In a preferred embodiment, the meta-bookmark 145 can include (or the personal data server 140 can otherwise provide), automated completion of forms and automated responses to applets, JavaScript or Java applications. This allows the individual user to provide access information to be used by the personal data server 140, either in
15 conjunction with use of a meta-bookmark 145 or otherwise, in which the web site 130 uses a technique for access to the personalized information that is relatively more interactive than providing a cookie, login name or password.

Method of Operation

20

Figures 6 and 7 collectively show a process flow diagram for a method of using a system for summarization and aggregation of personalized information.

A method 200 is performed by the system 100. Although the method 200 is
25 described serially, the steps of the method 200 can be performed by separate elements in conjunction or in parallel, whether asynchronously, in a pipelined manner, or otherwise. There is no particular requirement that the method 200 be performed in the same order in which this description lists the steps, except where so indicated.

30 Access to Jump Page

At a flow point 210, the personal data server 140 is ready to receive a request from an individual user for personalized information.

At a step 211, the individual user manipulates a web client 110 so as to access the communication network 120 and establish a connection between the web client 110 and the personal data server 140.

5

At a step 212, the personal data server 140 identifies and authenticates the individual user at the web client 110. In a preferred embodiment, the personal data server 140 can perform this step using a cookie stored at the web client 110, or using a login name or password for the individual user, a digital identifier, or any other form of identification and authentication.

10

For example, the digital identifier can include one for a hardware device operating as part of the web client 110, including a processor, a cellular telephone EIN, a caller-ID telephone number, or an identifier from an Internet service provider. This would be useful when the web client 110 is operating in conjunction with a device not directly coupled to the Internet, such as a handheld computer (such as a Palm Pilot), a pager, or a telephone (cellular or with interactive voice response).

15

At a step 213, the personal data server 140 retrieves, from its access database 142, access information for the individual user.

20

At a step 214, the personal data server 140 uses the access information to contact each web site 130 associated with the individual user, and to obtain personalized information for that individual user.

25

At a step 215, the personal data server 140 dynamically, in response to the personalized information it gleaned in the step 214, generates a jump page 144 for the individual user. As part of this step, the personal data server 140 computes or determines any aggregate information, in response to a profile it maintains for the individual user (or in response to a request by the individual user), for inclusion on the jump page 144.

30

At least a portion of the jump page 144 can be prepared in advance of the request made by the individual user, such as prepared in advance at a selected time of day or

at a selected frequency. Moreover, at least a portion of the jump page 144 can be updated in response to a selected time of day, a selected frequency, at the request of the individual user, or in response to information from the web site.

5 At a step 216, the personal data server 140 sends the jump page 144 to the web client 110 so as to present the personalized information to the individual user for review.

10 At a step 217, the individual user manipulates the web client 110 to review the jump page 144, and determine whether to perform further operations with regard to the personalized information. If so, the method 200 proceeds with the next step. If not, the method 200 proceeds at the flow point 210 or the flow point 220 or the flow point 230.

15 At a step 218, the individual user manipulates the web client 110 to perform further operations with regard to the personalized information. As part of this step, the individual user can perform one or more of, or some combination of, the following operations:

- 20 • The individual user can select a hyperlink or pointer on the jump page 144 to “click through” to a selected web site 130 having personalized information. As part of this operation, the individual user can manipulate the web client 110 so as to interact directly with the web site 130 with regard to the personalized information (or other information).
- 25 • The individual user can save or send a hyperlink or pointer on the jump page 144 as a meta-bookmark 145.
- The individual user can review and manipulate personalized information at the web site 130 using the hyperlinks or pointers on the jump page 144.

30 At a flow point 220, the personal data server 140 is ready to receive a request from an individual user to alter access information or preferences.

At a step 221, similar to the step 211, the individual user manipulates a web client 110 so as to access the communication network 120 and establish a connection between the web client 110 and the personal data server 140. If the connection was already established at the step 211, this step is optional.

5

At a step 222, similar to the step 212, the personal data server 140 identifies and authenticates the individual user at the web client 110. If identification and authentication were already performed at the step 212, this step is optional.

10

At a step 223, the personal data server 140 dynamically, in response to the access information or preferences it maintains for the individual user, generates an access or preference page for the individual user, similar to the jump page 144.

15

The access data may include at least one or more of, or some combination of, the following: name, address, Social Security number, names and ages of children, clothing sizes, medical information pertaining to the user, their spouse or other family member, type, date and amount of past purchases, number and type of pets, income data, address of user's work, users work phone numbers, links to web sites, information gleaned from other web sites.

20

At a step 224, similar to the step 216, the personal data server 140 sends the access or preference page to the web client 110 so as to present the access or preference information to the individual user for review.

25

At a step 225, similar to the step 217, the individual user manipulates the web client 110 to review the access or preference page, and determine whether to perform further operations with regard to the personalized information. If so, the method 200 proceeds with the next step. If not, the method 200 proceeds at the flow point 210 or the flow point 220 or the flow point 230.

30

At a step 226, similar to the step 218, the individual user manipulates the web client 110 to perform further operations with regard to the personalized information. As part

of this step, the individual user can perform one or more of, or some combination of, the operations described with regard to the step 218.

5 At a flow point 230, the personal data server 140 is ready to receive a request from an individual user to allow access to personalized information by other entities.

10 At a step 231, similar to the step 211, the individual user manipulates a web client 110 so as to access the communication network 120 and establish a connection between the web client 110 and the personal data server 140. If the connection was already established at the step 211, this step is optional.

15 At a step 232, similar to the step 212, the personal data server 140 identifies and authenticates the individual user at the web client 110. If identification and authentication were already performed at the step 212, this step is optional.

 At a step 233, the personal data server 140 records the request from an individual user to allow access to personalized information by other entities.

20 At a step 234, similar to the step 211 through the step 218, an entity other than the individual user can establish a connection with the personal data server 140, identify and authenticate itself as an entity authorized to review personal information for one or more individual users, and access that personalized information. In a preferred embodiment, the personal data server 140 allows only aggregate or otherwise limited access to the personalized information, as directed by the individual user.

25 For example, the individual user might choose to aggregate medical information or aggregate information concerning family pets. Limited access to aggregated information ensures that only relevant information is sent to the other entity. Thus, aggregating medical data for family members and veterinary data for pets, the individual user
30 can restrict their childrens' medical records from being set to a veterinary service.

 The method 200 continues at the flow point 210 or the flow point 220 or the flow point 230.

Generality of the Invention

The invention has general applicability to various fields of use, not necessarily
5 related to e-commerce as described above. For example, these fields of use can include one
or more of, or some combination of, the following:

- 10 • Access to census, demographic, marketing, or other population information – personalized
information regarding individual users (in these or related fields) can be reviewed and
manipulated by individual users or other entities. Similarly, personalized information
regarding individual users in other fields, such as medical or psychological information; or
teaching, training, or other skill-graded data (such as college records) can be reviewed and
manipulated by individual users or other entities.
- 15 • Use in conjunction or parallel with automated form completion – the individual user can
use personalized information (either aggregated, limited, or not), to conduct automated
form completion, without having to repeatedly provide that information. Similarly, the
individual user can permit access to personalized information (either aggregated, limited,
or not), by other entities to facilitate these or related techniques.
- 20 • Use in conjunction or parallel with e-commerce – the individual user can use personalized
information (either aggregated, limited, or not), to conduct e-commerce without having to
repeatedly provide that information. Similarly, the individual user can permit access to
personalized information (either aggregated, limited, or not), by other entities to facilitate
25 e-commerce.
- Use in conjunction or parallel with inter-user communication – the individual user can use
personalized information (either aggregated, limited, or not), to conduct inter-user
communication, such as bulletin boards or mailing lists, electronic “chat,” interest groups,
30 or related techniques, without having to repeatedly provide that information. Similarly,
the individual user can permit access to personalized information (either aggregated,
limited, or not), by other entities to facilitate these or related techniques.

Other and further applications of the invention in its most general form, would be clear to those skilled in the art after perusal of this application, and are within the scope and spirit of the invention.

5

IV.

Lexicography

The following terms refer or relate to aspects of the invention as described below. The descriptions of general meanings of these terms are not intended to be limiting,
10 only illustrative.

15

- **automated new-user registration** — in general, a technique for registering a new user with a web site, in which personalization information about the user is sent to the web site in an automated manner and without need for substantial user input

20

- **data input** — in general, sending data from a web client to a web site that requests that data

25

- **descriptive text** — in general, text or other descriptive presentation information (such as a graphic, a picture, or an icon) indicative of the nature of data requested for a selected field of a structured data input form

30

- **differing types of structured data forms** — in general, structured data forms having differing purposes, such as (1) requesting information to register a new user with a web site, (2) logging in an already-registered user with a web site, or (3) completing, approving or confirming an e-commerce transaction
- **forms for structured data input** — in general, a structured presentation, such as a graphic or picture, used to request data input from a user (typically an HTML or XML form)

- **helper application** — in general, software at the web client used to assist the personalization software in recognizing web pages and differing types of structured data forms

- 5
- **input field** — in general, a logical data field designated to request selected types of information from the user

- **logical field value** — in general, a logical descriptor of a type of information requested for a selected input field

10

- **meta-bookmark** — in general, a command, selected through a bookmark or another user interface element at the client, that associates a selected web page or URL, such as a current web page or URL, with a script or program fragment for taking selected actions with regard to that web page or URL

15

- **multiple or partial data values** — in general, a reassignment of partial data values or multiple data values for a single selected input field of a structured data form, such as distinguishing (year, month, day) for a single value of (date), or combining multiple values of (address, state, country) into a single value of (postal address)

20

- **personalization server** — in general, a device used to assist the web client in sending personalized information to one or more web sites

25

- **personalization software** — in general, software at the personalization server or at the web client used to assist the web client in sending personalized information to a web site, which collects information about a user or sending the information directly from the personalization server to the web site

30

- **pre-recorded personal information** — in general, information used by the personalization software, describing the user of the web client

- **program fragment** — in general, software at the web client (such as JavaScript, a Java applet, or another type of macro language program) for performing a selected programmable activity with regard to a web page (or URL)
- 5 • **screen location** — in general, a positional reference in a presentation of data to the user, such as a selected line of a structured data form
- **user** — in general, an individual using or operating a web client
- 10 • **web browser** — in general, web client software for use by a user
- **web page for confirming an e-commerce transaction** — in general, a web page (whether statically or dynamically generated) having the purpose of requesting information for, or confirmation of, an e-commerce transaction
- 15 • **web page for new-user registration** — in general, a web page (whether statically or dynamically generated) having the purpose of requesting information about a new user to be registered at a web site
- 20 • **web page for user login** — in general, a web page (whether statically or dynamically generated) having the purpose of requesting information about a user who has already been registered at a web site

As noted above, these descriptions of general meanings of these terms are not
25 intended to be limiting, only illustrative. Other and further applications of the invention, including extensions of these terms and concepts, would be clear to those of ordinary skill in the art after perusing this application. These other and further applications are part of the scope and spirit of the invention, and would be clear to those of ordinary skill in the art, without further invention or undue experimentation.

30

System Elements

Figure 8 shows a block diagram of a system for automated and intelligent structured data input.

A system 100 includes a web client 110, a web site 120, a communication link
5 130, and a personalization server 160.

The web client 110 includes a processor, program and data memory, and mass storage, operating under control of web client software (not shown) to perform the functions of a web client or web browser. The web client is operated by a user 111, and includes an
10 input device 112 and a presentation device 113. In a preferred embodiment, the web client software can include the "Netscape Navigator" product from America On Line or the "Internet Explorer" product from Microsoft Corporation.

Similar to the web client 110, the web site 120 includes a processor, program
15 and data memory, and mass storage, operating under control of web server software (not shown) to perform the functions of a web server or web site. The web site 120 includes a set of web pages 121 for sending to the web client 110 (upon request of the web client 110), including at least one web page 121 having a structured data form 122 for requesting information from the web client 110.

20 The communication link 130 includes a technique for sending and receiving messages between the web client 110 and the web site 120. In a preferred embodiment, the communication link 130 includes an Internet, intranet, extranet, virtual private network, or other technique for communication. In a preferred embodiment, the communication link 130
25 operates using the HTTP protocol (or a variant thereof), so as to send and receive web page requests and web pages.

Similar to the web client 110, the personalization server 160 includes a processor, program and data memory, and mass storage, operating under control of
30 personalization software 140 to perform the functions described herein.

System Data Flow

Figure 9 shows a data flow diagram of the system for automated and intelligent structured data input.

The system 100 includes a set of data flows for sending and receiving
5 information between the web client 110 and the web site 120, using the communication link 130.

A data flow 210 includes a set of messages between the web client 110 and the web site 120, in which the web client 110 is assisted by a set of personalization software 140
10 logically local to the web client 110 to enter data for structured data forms, so as to send that data to the web site 120.

The web client 110 sends a message 211 to the web site 120, requesting a selected web page.
15

The web site 120 responds to the message 211 by sending a message 212 to the web client 110, presenting a structured data form and requesting information from the web client 110.

20 The web client 110 recognizes the structured data form, using the personalization software, which assists the user with data input.

The web client 110 collects the information responsive to the structured data form (whether from the personalization software or from the user) and sends a message 213
25 with that information to the web site 120. As part of doing so, the web client 110 can obtain the information from the personalization server 160 when that information is available at the personalization server 160, or from the user of the web client 110.

Once the information is sent to the web site 120, the data flow 210 is complete.
30

A data flow 220 includes a set of messages between the web client 110 and the web site 120, in which the web client 110 is assisted by the personalization software 140 to perform a program fragment associated with a meta-bookmark.

The web client 110 sends a message 221 to the web site 120 requesting a selected web page.

5 The web site 120 sends a message 222 to the web client 110 including the selected web page.

The personalization software 140 at the web client 110 performs the following tasks

10

- a portion thereof recognizes the selected web page;
- a portion thereof completes a form or other data entry for the selected web page at the web site;

15

and

- a portion thereof completes a form or other data entry for the selected web page at the client device.

20 Once the actions associated with the personalization software 140 are performed, the data flow 220 is complete.

A data flow 230 includes a set of messages to the web site 120, in which personalization software 140 at the personalization server 160 performs automated new-user registration for the user of the web client 110 at a plurality of web sites 120.

25

The personalization software 140 sends a message 231 from the personalization server 160 to a set of selected web sites 120 including a request for a new-user registration web page.

30

Each selected web site 120 sends a message 232 to the personalization server 160 including the new-user registration web page.

The personalization software 140 at the personalization server 160 responds to each new-user registration web page by sending a message 233 to the associated web site 120 including information for registering the user at that web site 120.

5 Once the user is registered at the plurality of web sites 120, the data flow 230 is complete.

A data flow 240 includes a set of messages between the web client 110 and the web site 120, in which a helper application 150 assists the personalization software in
10 recognizing differing types of structured data forms and directing the personalization software how to enter data for those differing types of structured data forms.

The web client 110 sends a message 241 to a selected web site 120 including a request for a selected web page.

15

The web site 120 sends a message 242 to the web client 110 including the selected web page.

The helper application 150 intercepts the selected web page, and determines if
20 the web page is a web page for user registration, a web page for user login, or a web page for confirming an e-commerce transaction. The helper application 150 so informs the personalization software 140.

The personalization software 140 exchanges a sequence of messages 243 with
25 the web site 120, in which the personalization software 140 sends information requested by the web site 120 to perform operations associated with the web page.

Once the operations associated with the web page have been performed, the data flow 240 is complete.

30

Method of Operation

Figure 10 shows a process flow diagram of a first method for operating a system for automated and intelligent structured data input.

A method 300 includes a set of flow points and steps.

5

At a flow point 310, the user operating the web client 110 is ready to be assisted by personalization software that identifies forms for structured data input and assists the user with data input.

10

At a step 311, the user operating the web client 110 selects a web page at the web site 120.

At a step 312, the web site 120 sends the web page to the web client 110.

15

At a step 313, personalization software 140 identifies the web page as including a structured data form for data input.

20

At a step 314, the personalization software 140 identifies each relevant input field in the form with a set of descriptive text. In a preferred embodiment, the descriptive text includes information presented as part of the web page for the user of the web client 110 to determine what information is being requested.

25

At a step 315, the personalization software 140 associates each set of descriptive text with a logical field value. In a preferred embodiment, the personalization software 140 references each set of descriptive text with a dictionary of likely descriptive text, and thereby associates each set of descriptive text with a logical field value. For example, where the descriptive text is the character string "NAME", the logical field value can indicate that the requested data is <name of user>.

30

At a step 316, the personalization software 140 associates each relevant input field in the form with a screen location for presentation, such as with a specific set of descriptive text or a specific logical field value responsive to a proximity relationship between screen location for title and content in the form. In a preferred embodiment, the screen

location can be a relative position with regard to a second screen location for a second set of descriptive text.

At a step 317, the personalization software 140 associates each screen location
5 with a logical field value. For example, the personalization software 140 can determine that a screen location for requesting <name of user> is likely to be placed above a screen location for requesting <address of user>.

At a step 318, the personalization software 140 associates each logical field
10 value with multiple data values or partial data values. For example, as noted above, the logical field values for <first name> and <last name> might be combined into a single logical field value for <name of user>.

At a step 319, the personalization software 140 identifies personalization
15 information associated with each logical field value, and sends that information to the web site 120 in association with each logical field value. In a preferred embodiment, this step is performed without requirement for substantial user input. In alternative embodiments, the user may be asked for confirmation (or for completing unknown values) of one or more items of data for such logical field values.

20

Figure 11 shows a process flow diagram of a second method for operating a system for automated and intelligent structured data input.

A method 400 includes a set of flow points and steps.

25

At a flow point 410, the user operating the web client 110 is ready to be assisted by personalization software that performs a meta-bookmark.

At a step 411, the user operating the web client 110 selects a web page at the
30 web site 120.

At a step 412, the web site 120 sends the web page to the web client 110.

At a step 413, personalization software 140 identifies the web page as being associated with a meta-bookmark (and thus being associated with a script or program fragment to be performed).

5 At a step 414, the personalization software 140 identifies the associated script or program fragment associated with the meta-bookmark. [*** on the server ***]

At a step 415, the personalization software 140 performs the associated script or program fragment associated with the meta-bookmark.

10

Figure 12 shows a process flow diagram of a third method for operating a system for automated and intelligent structured data input.

A method 500 includes a set of flow points and steps.

15

At a flow point 510, the user operating the web client 110 is ready to be assisted by personalization software that performs automated new-user registration for the user of the web client 110 at a plurality of web sites 120.

20

At a step 511, the personalization software 140 sends the message 231 to a set of selected web sites 120 including a request for a new-user registration web page.

At a step 512, each selected web site 120 sends the message 232 to the web client 110 including the new-user registration web page.

25

At a step 513, the personalization software 140 responds to each new-user registration web page by sending the message 233 to the associated web site 120 including information for registering the user at that web site 120.

30

Figure 13 shows a process flow diagram of a fourth method for operating a system for automated and intelligent structured data input.

A method 600 includes a set of flow points and steps.

At a flow point 610, the personalization software 140 at the web client 110 is ready to be assisted by the helper application 150 that assists the personalization software in recognizing differing types of structured data forms and directing the personalization software
5 how to enter data for those differing types of structured data forms.

At a step 611, the web client 110 requests a selected web page from the web site 120.

10 At a step 612, the web site 120 sends the selected web page to the web client 110.

At a step 613, the helper application 150 intercepts the selected web page, and determines if the web page is a web page for user registration, a web page for user login, or a
15 web page for confirming an e-commerce transaction.

At a step 614, the helper application 150 informs the personalization software 140 of the web page type.

20 At a step 615, the personalization software 140 responds to the web site 120, depending on the web page type. In a preferred embodiment, this step includes a sub-step 615(a), in which the personalization software 140 performs operations suited to a web page for user registration; an alternative sub-step 615(b), in which the personalization software 140 performs operations suited to a web page for user login; and an alternative sub-step 615(c), in
25 which the personalization software 140 performs operations suited to a web page for confirming an e-commerce transaction.

Figure 14 shows a process flow diagram of a fifth method for operating a system for automated and intelligent structured data input.

30

A method 700 includes a set of flow points and steps.

At a flow point 710, the personalization software 140 at the personalization server 160 is ready to automate recognition of recognizing differing types of structured data forms and entering data those differing types of structured data forms directly from the personalization server 160.

5

At a step 711, the web client 110 requests a selected web page from the web site 120.

At a step 712, the web site 120 sends the selected web page to the web client
10 110.

At a step 713, the helper application 150 intercepts the selected web page, and determines if the personalization software 140 at the personalization server 160 is able to automate operations from the selected web page.

15

At a step 714, the personalization software 140 at the personalization server 160 automates operations, on behalf of the user of the web client 110, from the selected web page. As part of this step, the personalization software 140 at the personalization server 160 determines the type of the web page (similarly to the method 600) and responds to the web
20 site 120 (similarly to the method 600). In a preferred embodiment, this step includes the performance by the personalization software 140 at the personalization server 160 of all operations needed to perform operations for the selected web page (and any successor web pages), so that the user need not enter substantial data to perform operations for the selected web page.

25

For example, when the web client 110 is a wireless device for which it is relatively difficult to enter large amounts of data, the personalization software 140 at the personalization server 160 can automate (a) the entire process of logging the user of the web client 110 into a web site, and (b) the entire process of completing and confirming an e-
30 commerce transaction at the web site on behalf of the user of the web client 110.

Generality of the Invention

The invention has general applicability to various fields of use, not necessarily related to the services described above. For example, these fields of use can include one or more of, or some combination of, the following:

- 5 • information transactions and interactions relating to database queries and responses;

and

- information transactions and interactions relating to wireless devices and servers responsive thereto

10

Other and further applications of the invention in its most general form, would be clear to those skilled in the art after perusal of this application, and are within the scope and spirit of the invention.

15

I, II, III, and IV.

Alternative Embodiments

20

Although preferred embodiments are disclosed herein, many variations are possible which remain within the concept, scope, and spirit of the invention, and these variations would become clear to those skilled in the art after perusal of this application.

Claims

1. A method for access to a plurality of network services, said method including steps for
5 recording a set of authentication information in a database;
receiving a request to access at least one of said plurality of network services;
and
sending, in response to said request to access, said set of authentication information to said at least one of said plurality of network services;
10 whereby a user can maintain a single set of authentication information for said plurality of network services.

2. A method as in claim 1, wherein said steps for sending include steps for routing said set of authentication information through said web client.

3. A method as in claim 1, wherein said steps for sending include steps for routing said set of authentication information directly to said at least one network service without routing said information through said web client.

4. A method as in claim 1, said method including steps for providing a plurality of profiles of information for one said user; selecting one said profile; and
20 wherein said profiles include personalization information, and including steps for sending said personalization information in response to said steps for selecting one said
25 profile.

5. A method as in claim 1, said method including steps for providing a corresponding plurality of identifiers for said network services, in response to a request;
30 receiving a selection of one said identifier;
making a request to access an associated network service in response to said selection.

6. A method as in claim 5, wherein
said plurality of identifiers includes a page for presentation to said user; and
said step of selecting includes picking one or more of said plurality of
identifiers from said page.

5

7. A method as in claim 1, wherein
said database is maintained at a server;
said request is sent from a web client to said server, in response to a request by
a user at said web client;

10 whereby said server maintains said set of authentication information on behalf
of said user.

8. A method as in claim 7, wherein said server is logically remote from
said web client.

15

9. A method as in claim 7, wherein said web client includes a web server
device acting on behalf of said user.

10. A method as in claim 1, including steps for
20 receiving a request to newly access at least one network service not in said
plurality;
sending, in response to said request to newly access, a set of personalization
information to said at least one network service not in said plurality;
whereby said user is registered at said at least one of network service not in
25 said plurality without said user having to directly enter said set of personalization information.

11. A method as in claim 1, including steps for
receiving a request to again access at least one network service in said
plurality;
30 sending, in response to said request to again access, said set of authentication
information to said at least one network service in said plurality;
whereby access for said at least one network service is granted to said user
without said user having to directly access said set of authentication information.

12. A method for enforcing restricted access to a network service, said method including steps for

identifying a network service having access thereto restricted to a first set of
5 users;

identifying, for one of said first set of users, a second set of users to have access to said network service;

receiving, from one of said second users, a request for access to said network service; and

10 providing access to said network service to said one second user in response to said steps for identifying a second set, and in response to access permitted to said one first user identified therewith.

13. A method as in claim 12, wherein said steps for providing access to
15 said one second user include steps for

identifying a set of restrictions on said access to said one second user; and
restricting said access to said one second user in response to said set of
restrictions.

20 14. A method as in claim 13, including steps for altering said set of restrictions in response to a selection by said one first user.

15. A method as in claim 13, including steps for providing access to said
one second user in response to access permitted by any one of a plurality of said first users.

25 16. A method as in claim 13, including steps for providing access to said one second user in response to whether said one second user has access permitted by said one first user, or in response to whether said one second user is a member of said set of first users.

30 17. A method as in claim 13, wherein said network service includes at least one web site.

18. A method as in claim 13, wherein said set of restrictions include at least one time parameter.

19. A method as in claim 13, wherein said set of restrictions includes at least one type of access permitted to said one first user and denied to said one second user.

20. Apparatus for access to a plurality of network services, said apparatus including

a personalization server having a database, said database including information regarding a plurality of network services, information regarding a set of authentication information associated therewith;

said personalization server being disposed for receiving a first message requesting access to one of said network services, and for sending a second message to said one network service in response thereto, said second message including said set of authentication information;

whereby a user can maintain a single set of authentication information for said plurality of network services.

21. Apparatus as in claim 20, wherein said personalization server is disposed for routing said set of authentication information through said web client.

22. Apparatus as in claim 20, wherein said personalization server is disposed for routing said set of authentication information directly to said at least one network service without routing said information through said web client.

23. Apparatus as in claim 20, including accessible by said personalization server, a plurality of profiles of information for one said user;

said personalization server being disposed for receiving a selection message selecting one said profile, and for selecting said set of authentication information or a set of personalization information in response to said selection message.

24. Apparatus as in claim 20, including

a page for presentation to said user including a corresponding plurality of identifiers for said network services;

said personalization server being disposed for making a request to access an associated network service in response to receiving a selection of one said identifier.

5

25. Apparatus for enforcing restricted access to a network service, said apparatus including

a database associating a set of network services with a first set of users having access to said network services, said database associating one of said first set of users with a
10 second set of users to have access to said network service; and

a personalization server disposed for providing access to one said network service in response to one said second user and in response to said database.

26. Apparatus as in claim 25, wherein said database includes a set of
15 restrictions on said access to said one second user.

27. Apparatus as in claim 26, wherein said network service includes at least one web site.

20 28. Apparatus as in claim 26, wherein said set of restrictions include at least one time parameter.

29. Apparatus as in claim 26, wherein said set of restrictions includes at least one type of access permitted to said one first user and denied to said one second user.

25

30. A method of doing business, including steps for obtaining a single registration for a set of primary users for a group of related services provided by one or more processors coupled to a network;

enforcing restricted access to said single registration for a set of secondary
30 users associated with said primary users; and

providing said restricted access to said secondary users in response to registrations by said secondary users for said restricted access to said services.

31. A method of doing business, including steps for
maintaining a plurality of profiles for a user;
obtaining a plurality of registrations for said user for services provided by one
or more processors coupled to a network;
5 wherein said plurality of registrations includes information from at least two of
said profiles.

32. A method of doing business, including steps for
maintaining, at a personalization server, a plurality of registrations for a user
10 for services provided by one or more processors coupled to a network;
providing access to said services using said personalization server, in response
to requests from said user;
whereby said user can make said requests from more than one of a plurality of
devices coupled to said network.

15 33. A method including steps for
designating a group of web clients for group access to web sites;
receiving a selection of a web page for presentation to web clients in said
group; and
20 retrieving and presenting said web page to said web clients in said group.

34. A method as in claim 33, wherein said steps for retrieving and
presenting include sending at least part of said web page directly from a web server to at least
one web client in said group.

25 35. A method as in claim 33, including steps for
designating a controlling web client, wherein said selection of said web page is
received from said controlling web client;
receiving a selection of a web page for presentation to said controlling web
30 client without presentation to all said web clients; and
retrieving and presenting said web page to said controlling web client.

36. A method as in claim 33, including steps for

designating a controlling web client, wherein said selection of said web page is received from said controlling web client;

receiving a selection of a restricted-access web page from said controlling web client, said restricted-access web page including access control disallowing access to at least
5 one web client in said group;

obtaining access to said restricted-access web page on behalf of said controlling web client; and

retrieving and presenting said restricted-access web page to said web clients in said group.

10

37. A method as in claim 33, including steps for sending information relating to web sites between at least two of said web clients in said group, wherein said information includes web page bookmarks or web site registrations.

15

38. A method as in claim 33, wherein said group of web clients includes a plurality of differing types of web clients; said steps for receiving and presenting include receiving a plurality of variants of said web page, and steps for presenting one of said variants to each said web client.

20

39. Apparatus including a set of web clients; a group-surfing server disposed for receiving a selection of a web page at a web server, and for retrieving and presenting said web page to said web clients.

25

40. Apparatus as in claim 39, wherein said set of web clients includes at least one controlling web client and at least one non-controlling web client; said group-surfing server is responsive only to said selection of a web page from one or more controlling web clients.

30

41. Apparatus as in claim 39, wherein

said selection message indicates a restricted-access web page, said restricted-access web page requiring access control information disallowing access to at least one web client in said group;

an access message from said group-surfing server to said web site including
5 said access control information; and

a distribution message from said group-surfing server to said web clients in said group including at least some information from said restricted-access web page.

42. Apparatus as in claim 39, wherein

10 each of said web clients includes a program fragment disposed for recognizing a selection of a web link at said web server, and for sending a selection message to said group-surfing server in response thereto;

said group-surfing server retrieves at least part of said web page from said web server in response to said selection message.

15

43. Apparatus as in claim 42, wherein said program fragment is disposed for recognizing a post command from said web client, and for sending a message to said group-surfing server in response thereto.

20

44. Apparatus as in claim 10, wherein

said program fragment is disposed for recognizing a post command from said web client, and for sending a posting message to said group-surfing server in response thereto; and

25 said group-surfing server is disposed for receiving a plurality of said posting messages from a corresponding plurality of said web clients, and for sending a post command to said web server in response thereto.

30 45. In a method for presenting web pages to a plurality of web sites in conjunction, a data structure including identity or session information relating to a group-surfing server acting on behalf of said plurality of web sites.

46. A data structure as in claim 45, including a plurality of cookies received from web sites.

47. A data structure as in claim 45, including access control information not available to at least one of said plurality of web sites.

5 48. A method of doing business, including steps for
designating a group of web clients for group access to web sites, said group of
web clients being charged for said group access;
receiving a selection of a web page for presentation to web clients in said
group; and
10 retrieving and presenting said web page to said web clients in said group.

49. A method as in claim 48, including steps for
designating a controlling web client, wherein said selection of said web page is
received from said controlling web client;
15 receiving a selection of a restricted-access web page from said controlling web
client, said restricted-access web page including access control disallowing access to at least
one web client in said group;
obtaining access to said restricted-access web page on behalf of said
controlling web client;
20 retrieving and presenting said restricted-access web page to said web clients in
said group; and
charging said group of web clients for said access to said restricted-access web
page.

25 50. A method as in claim 48, including steps for
sending information relating to web sites between at least two of said web
clients in said group, wherein said information includes web page bookmarks or web site
registrations; and
charging said group of web clients for access to information related to web
30 sites.

51. A method including steps of
obtaining personalized information for an individual user, on behalf of said
individual user, from a set of web sites having said personalized information; and

presenting said personalized information to said individual user in a format other than available at said web sites.

52. A method as in claim 51, wherein said format includes at least one of:
5 aggregation or summarization of said personalized information, modification of said personalized information without direct interaction between said individual user and any of said web sites.

53. A method as in claim 51, including steps of
10 maintaining access information for said individual user for at least one of said web sites, said access information including sufficient information to perform said steps of obtaining; and

wherein said steps of presenting include steps of dynamically generating a presentation including (1) at least some of said personalized information and (2) interaction
15 information for said individual user to communicate directly with at least one said web site.

54. A method as in claim 53, wherein said interaction information includes at least one hyperlink to a web object at said web site.

20 55. A method as in claim 53, wherein said interaction information includes at least one hyperlink to a web object at said web site, said web object being an object requiring authentication or identification information for access from said web site, and said authentication or identification information being included in conjunction with said hyperlink.

25 56. A method as in claim 51, wherein said steps of presenting include steps of dynamically generating a presentation including information responsive to an aggregate of said personalized information from said web sites.

57. A method as in claim 56, wherein said aggregate includes at least one
30 of: a sum of account cash balances, a sum of account securities values.

58. A method as in claim 51, including steps of

maintaining access information for said individual user for at least one of said web sites, said access information including sufficient information to perform said steps of obtaining; and

presenting said personalized information to an entity other than said individual
5 in a format other than available at said web sites.

59. A method as in claim 58, wherein said steps of obtaining personalized information include steps of presenting said access information to said web site without delivering said access information to said entity.

10

60. A method as in claim 58, including steps of obtaining authorization from said individual user to present said personalized information to said entity.

61. A method as in claim 60, wherein said authorization is limited to at
15 least one of: aggregations of said personalized information, selected portions of said personalized information.

62. A method as in claim 58, including steps of
performing said steps of maintaining and obtaining for a plurality of said
20 individual users;
aggregating a set of results of said steps of performing said steps of obtaining for said plurality;
presenting an aggregate result of said steps of aggregating to said entity.

25 63. A method as in claim 62, wherein said aggregate result includes at least one of: account cash balance data, account securities values data, census data, polling data, market survey data.

64. A method of doing business, including steps of
30 obtaining personalized information for an individual user, on behalf of said individual user, from a set of web sites having said personalized information; and
making said personalized information available to said individual user in a transaction not requiring direct contact with those web sites.

65. A method as in claim 64, wherein said format includes wherein said format includes at least one of: aggregation or summarization of said personalized information, modification of said personalized information without direct interaction between
5 said individual user and any of said web sites.

66. A method as in claim 64, including steps of
maintaining access information for said individual user for at least one of said web sites, said access information including sufficient information to perform said steps of
10 obtaining; and
presenting said personalized information to an entity other than said individual in a transaction not requiring direct contact with those web sites.

67. A method as in claim 66, wherein said steps of obtaining personalized
15 information include steps of presenting said access information to said web site without delivering said access information to said entity.

68. A method as in claim 66, including steps of obtaining authorization from said individual user to present said personalized information to said entity, wherein said
20 authorization is limited to at least one of: aggregations of said personalized information, selected portions of said personalized information.

69. A method as in claim 66, including steps of
performing said steps of maintaining and obtaining for a plurality of said
25 individual users;
aggregating a set of results of said steps of performing said steps of obtaining for said plurality;
presenting an aggregate result of said steps of aggregating to said entity.

30 70. A method as in claim 69, wherein said aggregate result includes at least one of: account cash balance data, account securities values data, census data, polling data, market survey data.

71. Apparatus including
a personal data server including a set of personalized information for an individual user, said personalized information having been obtained from a set of web sites having said personalized information; and
5 a data structure including said personalized information in a format other than available at said web sites.

72. Apparatus as in claim 71, wherein said data structure includes at least one of: an aggregation or summarization of said personalized information, a hyperlink to a device for modification of said personalized information without direct interaction between
10 said individual user and any of said web sites.

73. Apparatus as in claim 71, including a data structure for said individual user, said data structure including
15 access information for at least one of said web sites, said access information including sufficient information to perform said steps of obtaining; and
interaction information for said individual user to communicate directly with at least one said web site.

20 74. Apparatus as in claim 73, wherein said interaction information includes at least one hyperlink to a web object at said web site.

75. Apparatus as in claim 73, wherein said interaction information includes at least one hyperlink to a web object at said web site, said web object being an object
25 requiring authentication or identification information for access from said web site, and said authentication or identification information being included in conjunction with said hyperlink.

76. Apparatus as in claim 71, including a data structure for said individual user, said data structure including
30 access information for said individual user for at least one of said web sites, said access information including sufficient information to perform said steps of obtaining; and

a data structure including said personalized information in a format other than available at said web sites.

5 77. Apparatus as in claim 76, wherein said personal data server is disposed for presenting said data structure to said entity without delivering said access information.

78. Apparatus as in claim 76, including authorization information for an entity other than said individual.

10 79. Apparatus as in claim 78, wherein said authorization information describes a limitation to at least one of: aggregations of said personalized information, selected portions of said personalized information.

15 80. Apparatus as in claim 76, including a data structure including an aggregate of said personalized information for a plurality of said individual users, for presentation to said entity.

20 81. Apparatus as in claim 80, wherein said aggregate includes at least one of: account cash balance data, account securities values data, census data, polling data, market survey data.

25 82. A method, including steps of
 accessing a web site from a web client device;
 executing a software module to identify a form at said web site for structured
 data input; and
 executing said software module to enter at least some data for said form
 without substantial user intervention.

30 83. A method as in claim 82, including steps of automatic registration of a user at a new web site, automatic login using the login page of a web site, or automatic form filling for checking out purchases from multiple web sites.

84. A method as in claim 82, wherein said software module includes at least a portion executed at a server device other than said web site.

85. A method as in claim 82, wherein said software module includes at least a portion executed at said web client device.

86. A method as in claim 82, wherein said web site includes a personalized web page only visible to a selected user after a login process at said web site.

87. A method as in claim 82, including steps of executing said software module to enter at least some said data at a plurality of distinct web sites.

88. A method as in claim 87, wherein said distinct web sites each include a web page for confirming an e-commerce transaction.

89. A method as in claim 87, wherein said distinct web sites each include a web page for new-user registration.

90. A method as in claim 82, wherein said software module attempts to perform at least one of:

associating at least one set of descriptive text for said form with a logical field value for said form;

associating at least one screen location for said form with a logical field value for said form;

associating at least one logical field value with a set of multiple data values or partial data values for said form.

91. A method as in claim 90, wherein said data values include a name, address, telephone number, credit card information, demographic information, preferred login name or password for said user.

92. A method as in claim 90, wherein said data values include pre-recorded personal information about the user.

93. A method as in claim 82, wherein said steps of accessing include recognizing a type of said form for structured data input; performing said step of executing said software module to enter at least some
5 data in response to a result of said step of recognizing.

94. A method as in claim 93, wherein said steps of recognizing include determining a difference between a web page for new-user registration, a web page for user login, and a web page for confirming an e-commerce transaction.
10

95. In a method for entering data in a form without substantial user intervention, a data structure including
an identifier of a web page;
an association of that web site location with a script or program fragment to be
15 executed for that web page;
whereby execution of said script or program fragment sends information to a server for entering data into said form.

96. A data structure as in claim 95, wherein said method includes
20 completing or confirming an e-commerce transaction at a web site associated with said web page.
